and regarded it as a most constant and valuable symptom of Bright's disease, but especially of the chronic forms. It was not entirely constant and continuous, but when absent an explanation could usually be afforded. To appreciate the symptom, much experience and constant practice were required, unless aided by instruments of precision, such as the sphygmograph, etc. In extreme cases the temporal arteries were hard and tortuous, and apt to present visible pulsations, and the radial artery felt like a tendon, or like the vas deferens.

The sphygmographs of Marey, Mahomed, and Pond were then exhibited and their practical use explained. The best sphygmograph in use was Brondel's.

HYPERTROPHY OF THE HEART.

Hypertrophy of the left ventricle of the heart was shown to be a very constant symptom. With malnutrition, the hypertrophy did not occur. Its absence might also be explained by the patient's general nutrition and the external conditions to which he was subject, and the same factors would influence the course and issue of the renal disease.

*Endarteritis chronica* was a very common symptom.

Certain diseases were associated with or were common to Bright's disease. Pneumonia occurring in persons over forty-five years of age was very frequently associated with Bright's disease. Cerebral hemorrhage in a person over fifty years of age was almost invariably associated with the small kidney. Peritonitis, when the common causes were excluded, was very commonly due to Bright's disease. Pericarditis, pleurisy, and cirrhosis of the liver, also might be associated with chronic Bright's disease.

AGE.

Acute Bright's disease occurred most frequently between the ages of one and forty years; chronic parenchymatous nephritis between the ages of thirty and sixty years; and chronic diffuse nephritis (small kidney and large white) between the ages of forty and eighty years.

Dr. McBride then spoke of

HEREDITARY INFLUENCE,

and quoted from Delafield to the effect that, while the disease might not be transmitted from father to son, it was very often found that a number of cases occurred in the same family. The disease also seemed to have a certain relation to chronic pulmonary phthisis; that is, some of the members of a family in which phthisis existed did not have consumption, but suffered from chronic diffuse nephritis. The sudden occurrence of *convulsions* might be the first symptom of the disease.

*Dyspepsia*, so frequently associated with chronic Bright's disease, was sometimes a cause and sometimes a consequence. Pain and uneasiness after taking food, flatulent distention of the bowels, constipation and diarrhœa alternately, were frequently attended with turbidity of the urine, small quantity, high colored, loaded with urates, which, after a time, gave way to a more copious discharge of urine, with low specific gravity, albumen, and granular casts. That view, entertained by Murchison, who quoted from George Johnson, was announced by Parks in the *Medical Times and Gazette* in 1854.

In the early diagnosis of chronic Bright's disease, the observer must give due attention: 1st, to age, hereditary influence, and other subjective symptoms; 2d, to objective symptoms, particularly the changes in the urine, increased arterial tension, diseased condition of the blood-vessels, cardiac hypertrophy; 3d, to the associated diseases or complications of Bright's disease; 4th, to the diseases to which chronic Bright's disease occurred secondarily; 5th, to the previous condition of the patient as to whether he had suffered from lithæmia, lead-poisoning, syphilis, or other poisons.

When that ground had been intelligently covered, the diagnosis of chronic Bright's disease could be arrived at in its earliest stages, and perhaps be appreciated while yet it had a functional existence.

'Dr. Austin Flint said that Dr. McBride's elaborate and comprehensive paper involved questions of great importance, and he would be pleased to have them discussed by deliberate papers on the practical part of the subject. The author of the paper had directed attention to those points which might lead to presumptive diagnosis, even before the changes in the urine and other phenomena which established the positive diagnosis were developed, a very important part of the subject. On the other hand, cases had been under Dr. Flint's observation in which a trace of albumen and casts in the urine had proved to be transient, and, although a great deal of uneasiness existed at the time lest they were the indications of structural changes, the symptoms had disappeared, and the persons had remained healthy. Another important aspect was the fact that in some cases only one uræmic effect was manifested prominently: for example, a frequently recurring intense cephalalgia.

Hypertrophy of the heart without valvular lesion he regarded as presumptive, almost conclusive, evidence of the existence of the cirrhotic kidney. Dyspnœa might be the only prominent symptom, and without any evidence whatever of pulmonary or cardiac affections furnished by physical examination of the chest. Again, cases presented themselves in which gastric symptoms only were present.

When the uræmic manifestation was thus developed in a single direction, there was great liability to errors in diagnosis.

Another interesting question in connection with chronic Bright's disease was the degree of tolerance exhibited in some cases.

Dr. Delafield thought there was a certain degree of danger in allowing ourselves to be influenced too much by the views and observations of English authorities. It was important to keep in mind the conditions under which diseases observed in England were somewhat different from what existed in this country. In England, the character of the climate, the race, the food, and the drinks, gave rise commonly to certain conditions which, indeed, were met with here, but not usually to anything like the same degree and extent as there. In England, the functional disorders of the liver, lithæmia and its attendant symptoms, the condition of high arterial tension, a very large amount

of hereditary gout, and the disposition which the climate gave to rheumatic diseases, all those produced, in a large proportion of the population, a certain train of symptoms; and besides that, the fact also that chronic diffuse nephritis was very common in England, as it is common in other temperate climates, the association of those two separate conditions had led English observers into a somewhat local way of putting together two factors which were not necessarily connected with each other. Because they had found in the same person the symptoms mentioned as belonging to functional disturbances of the liver, etc., and chronic Bright's disease, especially the atrophic form, they had mated the two conditions together, and Dr. Delafield thought that a great deal of confusion had arisen in that way. No matter how good English experience was, to a considerable extent it was local experience, and we should be somewhat careful how we extended it to what was seen here. There was one form of Bright's disease which was, perhaps, the most obscure of all; it was that which existed in those cases in which, for a number of years, there were absolutely no symptoms except loss of health, flesh, and strength. There might be neither gastric, cerebral, nor urinary symptoms; but, after a time the urine showed a slight trace of albumen, and this, perhaps, only after meals or after exercise, and other symptoms followed. The specific gravity of the urine in these cases was usually low from the beginning.

Another important point was the fact, which must be admitted, that the symptoms obtained during life were not entirely dependent upon the lesion in the kidney. We had to admit that the symptoms were due to two things: partly to the lesion in the kidney, and partly to the functional disturbance of the kidney, superadded to those produced by the lesion. For, a patient might die with the most marked symptoms of chronic Bright's disease, and at the autopsy only very slight lesions be found; and, on the other hand, patients died with absolutely no symptoms of Bright's disease, and at the autopsy the most marked lesions of the kidney were found. Besides, there was the ordinary clinical experience, that a patient with kidney-lesion continuously, would, part of the time, give symptoms, and a portion of the time give no symptoms whatever. It must be admitted, therefore, without hesitation, that the clinical symptoms, as met with, were due to something more than the mere lesion of the kidney, and that we had to deal with functional disturbances which were a large factor in the manifestions of the disease. That fact gave some encouragement with regard to treatment. If the symptoms were capable of being modified by changes in the functional disturbances, we might hope to be able to do something in that direction, and thus modify the suffering of the patient.

Dr. W. H. Draper thought that the early diagnosis of parenchymatous nephritis was not difficult, in many cases at least, inasmuch as, in the acute form especially, the case was apt to begin with more or less prominent symptoms which directed attention to the kidneys. He thought that it was with reference to the cirrhotic kidney that we needed means for making an early diagnosis; for, when the disease was diagnosticated, it had, as a rule, already made great progress. He regarded that part of the paper which dealt with functional disturbances preceding the appearance of albumen in the urine, and might precede even marked development of arterial change, as especially interesting, because those phenomena were most important elements in early diagnosis. He did not agree with the suggestion made by Dr. Delafield, that there was a very marked difference between the causes which led to the chronic forms of Bright's disease in this country and in England. He believed that we ate and drank as much, and had as many of those disturbances of the digestive organs which ultimately led to chronic disease of the liver and kidney, in this country as in England. His own experience, for a considerable time, had led him to believe that the functional disorders of the liver, as they were ordinarily described, had a great deal to do with the ultimate development of those changes seen in the arterial system and in the parenchymatous organs, and which terminated in chronic hepatic and renal disease. He had been inclined to believe that the observations of Gull and Sutton, on what they termed "arterial capillary fibrosis," had in their relation to chronic atrophy of the kidney a very important bearing. If their observations were well-founded, the idea suggested by Dr. McBride, that the long-continued irritation of the blood-vessels, by the circulation in the blood of irritant, imperfectly oxygenized nitrogenous matters, constituted the real and the primary element in the development of the atrophic kidney, was not unreasonable.

Another thing which had a tendency to make him believe in the influence of irritants in producing chronic kidney disease, was the fact that he had seen a considerable number of cases of cirrhotic kidney in persons who had been poisoned by lead. So far as that particular form of renal disease was concerned, he believed that Dr. McBride had brought a very important subject to the notice of the profession, namely, that the functional disorders of digestion, especially those which were accompanied by lithæmia, constituted the foundation of a very large proportion of the atrophic changes which occurred in the blood-vessels and parenchymatous organs.

Dr. W. H. Welch spoke of anatomical points which had a close connection with the symptoms and diagnosis of chronic Bright's disease. He called attention to the statement made by Dr. McBride, that some cases of chronic parenchymatous nephritis were insidious in their origin and development. Dr. Welch believed that a true chronic parenchymatous nephritis was a very rare disease, at least in New York, and that the cases which presented during life the symptoms, and after death the gross appearances, usually ascribed to that form of chronic Bright's disease ("large white kidney"), were, in the vast majority of instances, examples of a chronic diffuse nephritis. In his experience he had not failed to find interstitial changes, particularly thickening of Bowman's capsule, combined with the parenchymatous changes in all of these cases. He would not deny the occurrence of chronic parenchymatous nephritis, yet he believed that it was extremely rare, and he thought it quite probable that the cases referred to by Dr. McBride were really cases of chronic diffuse nephritis in which the kidneys presented the gross appearances of the "large white kidney" of English writers.

Another anatomical point was with reference to hypertrophy of the heart. It was a very prevalent view that hypertrophy of the heart was almost entirely confined to the small kidney. But, while it was much more frequently found with the small than with the large kidney of chronic diffuse nephritis, he thought that it was not so infrequent with large kidneys as was generally supposed. Certainly there were cases

in which the symptoms of chronic parenchymatous nephritis were well marked, and in which extensive hypertrophy of the left ventricle existed without valvular lesions; and he also believed that he was justified in stating that, in New York at least, hypertrophy of the heart, in connection with the large kidneys of chronic diffuse nephritis, was not of very infrequent occurrence.

Among the causes which Dr. McBride had adduced to explain the absence of cardiac hypertrophy in chronic Bright's disease, no mention had been made of the influence of waxy degeneration. It had been pointed out that cardiac hypertrophy was absent in all, or nearly all, the cases of chronic Bright's disease where waxy degeneration was an element, and thus it might aid in making a differential diagnosis.

With reference to the relation between disease of the arterial system and the small kidney, there could be no doubt that cases occurred which corresponded to Gull and Sutton's view, but there was not sufficient evidence that all of the cases of small kidney could be brought into that category. The form of arteritis which was present in cases of small kidney was often an obliterating endarteritis, and Dr. McBride, in speaking of endarteritis chronica as a frequent complication of chronic Bright's disease, had left us in doubt whether he referred to this form or not.

In illustration of those cases to which reference had been made, where some unexpected symptom or accident was the first evidence of chronic Bright's disease, Dr. Welch alluded to a case which had come under his observation. A man, not previously suspected to have Bright's disease, died suddenly from hæmatemesis. The autopsy revealed a pore-like opening in the gastric mucous membrane, leading to a miliary aneurism on a branch of one of the gastric arteries which had burst. In that case there was a wide-spread endarteritis obliterans combined with small kidneys and hypertrophy of the heart. Similar cases of obscure hemorrhage from the pulmonary organs, from the stomach, and from the intestines, had been reported in connection with the small kidneys, but in most instances no source for the hemorrhage had been discovered. Dr. Welch believed that the existence of miliary aneurisms would be found to explain many of these obscure cases.

Dr. A. L. Loomis believed that it was hardly possible to speak of the general symptoms of the different forms of degeneration of the kidneys under the single head of "chronic Bright's disease." From a clinical stand-point he had come to regard Bright's disease, if the general term was to be retained, as an affection which manifested itself in those classes of cases:

*First.*—A class in which the ordinary symptoms of the disease existed, such as well-marked œdema and other renal symptoms accompanying the œdema, and the disease progressing steadily to a fatal termination, as a common form of Bright's disease. It might be called chronic parenchymatous or chronic diffuse nephritis, or by any other name; but the number of cases belonging to this class was large, sometimes the disease began with acute symptoms, at other times it came on slowly, but in both œdema was constantly present from the beginning to the end, and with the œdema there were more or less changes in the urine—quantity variable, always containing albumen in small or large quantities, and quite constantly casts.

*Second.*—A class in which loss of flesh without any apparent cause, a rapidly growing-old condition, was the prominent symptom, with which the quantity of urine varied—not always large, not always below normal, sometimes of high specific gravity, at other times the specific gravity is much below normal—the variations being, seemingly, according to the surroundings of the patient and his mode of living, diet, etc., and yet he steadily lost flesh, labored under depression of spirits, and finally unmistakable evidence of kidney-lesion was found. That was the class of cases in which it was the most difficult to make a diagnosis.

*Third.*—A class of cases in which the symptoms were nervous from the beginning, manifested in various ways, and one of the most frequent was *insomnia*, which in some cases was so prominent that the patients resorted to anodynes to produce sleep. That class of cases came under the head of the atrophic kidney, which had been chiefly considered during the discussion. Headache, insomnia, and certain peculiar nervous symptoms characterized these cases long before any evidence of kidney-lesion was manifested by changes in the urine. In that class of cases the symptoms depended on diathesis, rather than upon lesion in the kidney, and the kidney-symptoms constituted the last page in their history. There might be disturbances in the fibroid element of the body—if such a term was allowable—going on for a long time, such as gave rise to high arterial tension, etc., without affecting the kidneys to such an extent as to interfere decidedly with their function. When he found that form of pulmonary phthisis in which it was evident that fibroid change in the lungs was taking place, he regarded it as but one link in a chain, and immediately instituted a special investigation with reference to the condition of the kidneys.

Hypertrophy of the heart was always found in the third class of cases, but it existed in the other forms of the affection, and very frequently in that variety described under the head of "large white kidney" (chronic parenchymatous nephritis), but it seemed to him that the cause of the hypertrophy in the two instances was different. In the cirrhotic kidney it was due primarily to arterial changes; in chronic parenchymatous nephritis, to interference with capillary circulation due to blood-changes.

In an article published in the *American Journal of Medical Sciences* for October, 1881, Dr. Da Costa, of Philadelphia, had pointed out in a clear manner the symptoms of lithæmia, and by studying those and attempting to draw the line of distinction between them and those symptoms which Dr. McBride had mentioned as affording early evidence of chronic Bright's disease, the difficulty could be easily appreciated.

When fibroid changes in the arteries and hypertrophy of the heart occurred before any renal symptoms which could be positively established, the patient might have been for a long time in that general condition which had had to do with the arterial- and the kidney-lesion. The more he saw of these cases, however, the firmer was his conviction that the kidney-symptoms were the last part of the history.

Dr. McBride, in closing the discussion, remarked that he believed it to be absolutely impossible in all cases to make a positive differential diagnosis between the large and the small kidney of chronic diffuse nephritis, and therefore he was compelled to include the large varieties of kidneys in his classification.

He again drew attention to the statement which he had made in his paper, that there were cases of chronic parenchymatous nephritis where a positive diagnosis was impossible, and also that the more chronic such cases became, the more likely were they to terminate in chronic diffuse nephritis. With reference to the frequency of lithæmia, gout, and gastro-hepatic disturbances in this country, he had found them extremely common, both in private and in dispensary practice, and all of the observations upon which his paper was based had been made in cases presenting such symptoms. He had not borrowed anything from English writers, except in corroboration of the views he had presented, and the conclusions he had reached from observing cases exclusively in this country.

With reference to the absence of symptoms until some accident occurred or intercurrent disease, the fact was mentioned in that part of his paper which he felt compelled to omit on account of time.

With reference to the relation of hypertrophy of the heart and the amyloid kidney, he omitted to mention it, because the consideration of the amyloid kidney was not embraced in his paper, although waxy degeneration might be present in the other forms of chronic Bright's disease.

With reference to endarteritis chronica, spoken of by Dr. Welch, he said that his subject had been studied simply from a symptomatological standpoint; that we had to deal only with the visible or palpable arteries; and that endarteritis chronica was an element in diagnosis only when appreciable in superficial arteries like the radials and temporals. Furthermore no cases of endarteritis obliterans had been reported in arteries of that size, and, so far as he knew, none had been reported of the retinal vessels, although Gowers had referred to thickening of the retinal arteries, but not obliteration. Dr. McBride thought, therefore, that arteritis obliterans in the kidney, lungs, and brain had no relation to the subject under discussion.

The Academy then adjourned.

## NEW YORK PATHOLOGICAL SOCIETY.

*Stated Meeting, October* 26, 1881.

DR. T. E. SATTERTHWAITE, PRESIDENT, IN THE CHAIR.

### THE QUESTION OF ABDOMINAL SECTION IN GUNSHOT WOUNDS OF THE ABDOMEN.

DR. GEORGE F. SHRADY presented specimens consisting of a portion of liver and a section of abdominal aorta, removed from the body of a young woman who committed suicide by an infliction of a pistol-shot wound of the abdomen. She was admitted to the Presbyterian Hospital at noon, October 20th, an hour after the injury, in a state of profound collapse. The point of entrance of the ball was in the left side, over the seventh costal cartilage, three and three-fourths inches below the nipple, and two and one-half inches from the median line. Dr. Simpson, the house surgeon, believing that the missile had entered one or other of the cavities, did not make any exploration of the wound.

When Dr. Shrady saw the patient, at 3 P.M., she was still suffering from shock. There was excessive pallor of the countenance, a small, tremulous pulse, heavy sighing respiration, coldness of the extremities, intense thirst, jactitation, and the other symptoms of internal hemorrhage. The wound, in the situation already indicated, was small and rounded, corresponding in size with that made by a ball of about twenty-two calibre, and was sealed by coagulated bloody serum. The surrounding integument was blackened by powder-grains. An inspection was made of the wound and surroundings in order, if possible, to ascertain the character and extent of the injuries inflicted. The persistence of the shock, with the accompanying symptoms, made it clear that there was internal hemorrhage, and that the seat of the same was below the diaphragm. For obvious reasons no attempt was made to explore the track of the missile. There were no evidences of wound of the lung by a possible upward direction of the bullet, nor was there any increased area of dulness over the heart. It was impossible to ascertain the position of the weapon when the charge was fired, but the natural assumption was that the ball took a general direction from before backward.

### THE DIAGNOSIS OF SUBPERITONEAL HEMORRHAGE.

The wound being over the region of the liver, an injury of that organ was suspected, but the occurrence of other symptoms pointing to extensive hemorrhage from another locality ruled out that organ as a prime factor in the complication. There were no symptoms of wound of the stomach. This was explainable only upon the supposition that the organ was empty and collapsed at the time the shot was fired. Percussion over the abdomen gave normal resonance, except in each lumbar region, where flatness existed, accompanied, especially on the right side, with an irregular tumor, the external presenting edge of which was reasonably firm and quite well defined. This condition, associated with a progressive and tearing pain, deeply situated in the abdomen, gave rise to the diagnosis, duly confirmed by the autopsy, of a dissecting subperitoneal hemorrhage, due to injury of one or more of the large vessels in the subperitoneal region. Assuming the course of the ball to be backward, downward, and outward, the left renal artery was believed to be the probable source of the bleeding.

The patient died in collapse twelve hours after the injury.

The necropsy was made thirteen hours after death, by Dr. W. H. Porter, Curator of the Hospital, who kindly furnished the accompanying report: Body well nourished and abundantly supplied with adipose tissue. Rigor mortis fairly marked. A small, blackish perforation in the skin of the left breast, two and three-quarter inches from the median line, three and three-quarter inches below the line of the nipple (bullet wound). Slight hypostatic congestion of the dependent portion of the trunk.

*Thoracic cavity.*—The pericardial sac contained half an ounce of clear serous fluid, slightly tinged with blood. The heart was nearly covered in by a thin layer of adipose tissue. Weight, nine ounces; organ normal in all respects.

Left pleural cavity contained two ounces of bloody serum. Left lung perfectly free from pleuritic adhesions; weight, eleven ounces. In the right pleural cavity there was half an ounce of bloody serum. A band of old pleuritic adhesions existed at the posterior border of the lung, at the fourth intercostal space, just external to the angle of the ribs; otherwise the lung was free; weight, eleven ounces. Both lungs were quite dry, but when cut into their central portions were bright red, as if deeply congested.

*Abdominal cavity.*—There was both bloody serum and coagulum in the peritoneal sac, seventeen ounces

of the former and one of the latter. The coagulated blood lay upon the right side on the free surface of the peritoneum, between the ascending colon and the root of the mesentery. Upon turning the small intestines to the right and out of the peritoneal cavity, a large subperitoneal extravasation was brought clearly into view, lying between the descending colon and the root of the mesentery. This extravasation appeared to extend from the splenic flexure of the colon downward and to the right, apparently terminating at the superior border of the right broad ligament. Later on it was traced downward and outward through the great sacro-sciatic foramen. All the post-peritoneal and the perinephritic tissues were filled with blood-clots and serum, the kidneys being fairly embedded in a mass of coagulum. The *liver* was very pale, as if bloodless; otherwise normal, excepting the hole made by the ball.

The course of the ball was from before backward and to the right, through the centre of the seventh costal cartilage into the pleural cavity, diaphragm, and cavity of the abdomen. It thence tracked through the liver, one inch from its longitudinal fissure, passed the lesser curvature of the stomach, slightly wounding its muscular coat, cleared the superior border of the pancreas, splenic artery, and posterior surface of the duodenum, and perforated the anterior wall of the abdominal aorta a little to the right of the median line, and an inch below the origin of the right renal artery. The point of exit from the aorta was on the right posterior aspect of the vessel. The bullet evidently struck the body of the second lumbar vertebra, and was deflected from its course in a direction downward and outward into the substance of the right psoas muscle.

Its point of lodgement was three inches below the wound in the artery and two and a half inches to the right of the median line.

Quite naturally, in view of recent discussions bearing upon the propriety of performing abdominal section in such cases, this measure was thought of by Dr. Shrady when the patient was first seen. For many reasons the expediency of such an operation was not entertained. There was no doubt that internal hemorrhage was taking place, and that the patient was dying in consequence, still it was quite plain that she was beyond the possibility of aid by any operation. Although the location of the clot was diagnosticated before death, and the source of the hemorrhage was discovered post-mortem, scarcely an inch from the supposed locality of the injured artery, any attempt at tying the vessel actually wounded, even if reaction had been previously established, would have been worse than useless.

Dr. Shrady remarked that the case exemplified, in quite a striking manner, the usual contraindications for the operation of abdominal section in gunshot wounds of the abdomen. These were briefly alluded to as persistence and profundity of shock, difficulties of diagnosis as to the organ wounded, the degree and source of the hemorrhage, the precise track of the missile, and also the danger of adding to existing evils by any attempts at exploring the wound.

Dr. Briddon said that until within the last few years the large serous cavities had justly been regarded as closed, or sealed sacs, so far as surgical interference with them was concerned. It was to the results obtained under the antiseptic treatment, doubtless, that the heroic measures could be traced which were now regarded as justifiable and proper in some cases of wounds of these cavities. It was one thing to picture an ideal case of such a wound, with the consequences standing out in bold relief, symptoms all clearly defined, everything represented in beautiful outline, such, for instance, as those depicted in the various text-books. Such an assemblage of conditions might warrant the inauguration of a line of treatment which an autopsy would sustain. His impression was that, in the large majority of cases, when we come face to face with realities, the situation would be different. We should find no such accommodating association of facts to guide us, and with everything obscure and doubtful, provokingly so in most cases, the patient in profound collapse (how much due to impressions made on the great system of nerves that preside over the functions of the viscera, and how much due to hemorrhage, it was impossible to decide), and with little else to guide him, he would be bold who would advise and perform a section that might, by adding to the shock already existing, strangle the reaction which was struggling for existence; a section which also might expose to view a condition of affairs far different from that supposed to exist, thus giving evidence of the fallability of human judgment; and of a state of affairs that would lay the operator open to the charge of meddling with conditions the gravity of which he had no previous adequate idea. Some years ago he had heard a member of the society, now dead, but then eminent in the profession, declare that he should hold the man who would stand by the bedside of a woman dying from hemorrhage due to rupture of a Fallopian tube, in gestation occurring within that canal, and who would refuse to open the abdominal cavity and secure the bleeding vessels, guilty of manslaughter. The terms were strong, and he (Dr. Briddon) thought they could not be sustained. For, often when the surgeon saw such a case the hemorrhage had ceased by natural processes, and the collapse was so great that the additional shock of such an operation might well be regarded as dangerous; besides there were well authenticated cases where recovery had followed even so grave an accident as this. He could conceive cases such as might demand interference to stay a hemorrhage going on immediately after the reception of a wound. He would also advise abdominal section in wounds of the intestine. Of course, in wounds of protruded viscera the indications were plain enough to suture the intestine and return it to the cavity. In those cases in which we have evidence of fecal extravasation within the abdomen, he had no doubt the proper course to pursue was to open the cavity and either suture and replace the gut, or secure it in the abdominal wall and aim for an artificial anus. He could also conceive of a condition met with when the patient was coming out of collapse, when reaction was being established, when the abdomen was becoming distended with the products of inflammation due to unrecognized extravasation; under such circumstances he thought it would be proper to make abdominal section, seek, and secure the intestinal wound, wash out the cavity with antiseptics, and introduce either glass or rubber tubes to insure drainage. The proper time to interfere was either when hemorrhage was going on or at a later period, when we had reason to fear that peritonitis, due to extravasation, was either present or impending.

### PROBING WOUNDS OF CAVITIES.

Dr. Howe asked Dr. Shrady what objection he had to passing a probe through a wound into the abdominal cavity.

Dr. Shrady replied that on general principles it was bad practice, and nothing could be gained by the procedure.

Dr. Howe asked, "Why bad practice?"

Dr. Shrady replied: "Because it may add to already existing evils."

Dr. Howe remarked that that was only a supposition. He was unable to see what harm a Nélaton probe would do following in the track of a greasy bullet through the abdominal walls into the cavity, if it was passed by gentle hands. Were he called to a case of gunshot-wound, no matter where it was, provided the patient was alive and not in profound collapse, he would introduce a probe and endeavor to find the track of the bullet without twisting the instrument about or searching in a rough way in any organ. For, if the ball was allowed to remain it certainly would cause harm and greater damage than would be done by the probe carefully used.

If the bullet could be located he did not see why the surgeon should not enlarge the opening, if necessary, and remove it. Besides, the probe might give some indication as to whether or not the intestines were wounded; for if fecal matter had escaped into the abdominal cavity, the instrument might come in contact with it and bring some of it out, and thus afford a good indication for an operation.

Dr. Howe also thought that a surgeon might be justified in making abdominal section in cases of wounds of the gall-bladder. If left untouched, they were certain to terminate fatally; while it was possible that the patient's life might be saved by opening the abdomen, closing the wound in the gall-bladder, or bringing the edges of the opening into the lips of the abdominal incision and securing them with sutures.

He believed that the same course was justifiable in connection with wounds of the kidney, and also of the bladder, as well as of wounds of the intestines. The mere fact that a case was found post-mortem which could not have been benefited by an operation did not prove anything against proper probing.

Dr. Briddon's opinion was that any proposition to probe the abdominal cavity, after gunshot-wound, was vetoed by the profession, that it was settled long ago, and that the condemnation of such a proceeding was most emphatic; it could do harm by increasing extravasation in wounded intestine, by disturbing clot in vessels that had given rise to hemorrhage, and was a most fallacious and unreliable guide in every respect. He could conceive of no conditions that would warrant its use. With reference to wounds of the gall-bladder or its ducts, he did not regard them as of necessity fatal.

Dr. Howe said that there was no such general rule; there was probing and probing, but gentle probing had not been objected to by any one.

Dr. Shrady believed it to be a good rule not to probe large cavities into which the surgeon was sure a bullet had entered; for, by probing, he was more apt to do harm than good. If, for example, an attempt should be made to probe a wound of the abdominal cavity, there would be much difficulty and uncertainty in following the track made by the ball, and the chances would be fair that some vessel would be wounded, some clot disturbed, or some important organ injured, and in the end the locality of the ball be undetermined. He was glad that he had not attempted to introduce the probe in the case reported, because it certainly would have entered the liver and doubtless increased the hemorrhage. He was satisfied that internal hemorrhage was taking place, also that the bullet had occasioned it; that it was impossible to locate either the missile or the wounded vessel; and he was therefore forced to leave the case to nature. Furthermore, he believed that the autopsy vindicated the plan of management adopted.

Dr. Howe regarded Dr. Shrady's case as an exception to the rule, because the course of the bullet and what was killing the patient were known. He wished his remarks to be applied to cases in which the surgeon was ignorant of the track of the bullet; and in such cases he believed that, if the patient was not in a state of profound collapse, the surgeon would be justified in following the ball with a probe until he became satisfied that he was unable to find where it had lodged.

Dr. Shrady thought that the great difficulties in such cases were in making a positive diagnosis, and in obviating the condition of shock which would render any operation admissible. Under such circumstances the benefit of the doubt should be given to the patient rather than to the surgeon.

The President said that his experience had been confined to penetrating wounds of the thorax, but so far as it had extended it had led him to favor sealing them hermetically with collodion. He had seen four cases while an interne in the New York Hospital. In three of them the opening was kept patent, and all the patients died with empyema and pneumonia. In the fourth case the wound was tightly sealed with collodion, and although empyema and pneumonia supervened, the complications were less severe than in the other cases, and the patient recovered.

Dr. Briddon had seen five or six cases in which there was a penetrating wound of the chest-wall, in some of them the viscera being involved, and they had entirely recovered without any local treatment whatever. The ball was small, and the wounds did not require the application of collodion, for they were sealed effectually by natural processes.

Dr. Howe said that such experience could not be used as an argument against entering the abdomen. For, in the first place there was no poisonous substance like fæces or bile or urine to be poured out; there was nothing except the blood to be extravasated, and it was a well-known fact that patients with bullet-wounds of the lungs frequently recovered without special treatment. It was also a well-known fact that bullet-wounds of the intestines, gall-bladder, kidneys, etc., were almost always fatal; the patient having next to no chance whatever of recovery. Why should we not give the patient one chance?

(To be continued.)

The Cure of Aneurism of the Aorta by Galvano-Puncture is so rare that a case of this kind, under care of Dr. Richard Cameron, of Valparaiso, Chili, deserves notice. The patient was a man of forty, with an aneurism of the ascending arch. The usual remedies were tried without success, and galvano-puncture was finally resorted to.

Two fine steel gilt needles were used, passed into the aneurism, and kept there for twenty minutes. In about two weeks the tumor began to flatten, and all bad symptoms gradually and permanently disappeared.

The curious and instructive point is that, after removal of the needles, it was found that almost no current had been passing, owing to a defect in the battery.

## HYPODERMIC MEDICATION.

### How Hypodermic Injections should be Administered and Prepared.

To the Editor of the Medical Record.

Sir: In recent numbers of The Medical Record I have noticed several communications from correspondents on the subject of the hypodermic use of morphia, and it has occurred to me that the results of my own quite extensive experience in a similar use of this and other remedies might not be wholly devoid of interest or value, at least to a portion of the profession. What I have to say probably will not be new to many practitioners, but that to a far larger number it will be, I am convinced by daily observations.

First, with regard to the remedy most frequently administered hypodermically—morphia: the following solution, the formula which I find in my notebook under date of 1875, credited to Skidmore, a druggist of Portland, Oregon, and with whom, so far as I know, it is original, is a perfectly stable one, never showing signs of change or of the growth of fungus after years of keeping, and never producing inflammation or even irritation when given in the manner shortly to be mentioned.

℞ Morphiæ sulph.....gr. xcvi.
Aq. destillat. ebul..... ʒ iij.
Acid sulph. dil..... ♏ viij.
Misce et adde
Acid. carbolic.....gr. xx.
Glycerin. pur..... ʒ j.
Cola per chart.

Of this, twenty minims contain one grain. The only objection to the use of this solution which I can see, is that it might be confounded with the somewhat weaker Magendie's solution, but that risk could be readily obviated by diluting the one to the strength of the other.

A solution which will keep perfectly well, for several months at least, can be made by the addition of carbolic acid to the ordinary Magendie's solution, as Dr. Gillette states in The Record of October 1st, or by using chloral hydrate, salicylic acid, or probably any other equally harmless germicide. All of the above I have used, including the salicylic acid, about which some doubts have been raised, and find them all entirely satisfactory; but more than that, I have very frequently been compelled to use the ordinary solution, old and full of the much-dreaded vegetable growth, obtained at drug stores in little towns on the remote frontier, at military posts and on the march with troops in the field—solutions which, if used in the ordinary manner, would almost inevitably have produced cellulitis, and probably abscess, and, for more than six years, no one of the great number of hypodermic injections of morphia made by me has been followed either by abscess or cellulitis, however slight.

There can be, I think, but one explanation for this somewhat exceptional experience, and that is the manner of administering the injections, which is as follows:

Taking good care *not* to allow any of the solution to escape into the subcutaneous cellular tissue, the needle of the charged syringe is plunged *deeply* into the substance of some muscle, ordinarily the deltoid. the piston gently pressed home, and the needle withdrawn.

The thick muscles of the thigh, the gluteal region, or the back can be made the site of the injection equally as well, but as the deltoid is very easily accessible under all circumstances, it is the one usually selected.

As every one knows, the subcutaneous cellular tissue is always easily inflamed, and in certain conditions of the system the most trifling injury to it is sufficient to set up an inflammation of which suppuration is by far the most frequent termination. I am satisfied that cases are continually occurring in practice in which an abscess is sure to follow a hypodermic given in the ordinary way, no matter how deft the operator, how scrupulously clean the needle, or how thoroughly bland and unirritating the solution used. On the other hand, the muscles are exceedingly slow to take on inflammation, and suppuration in this tissue, even after very severe injuries, is extremely rare if the skin is unbroken, or practically so, as in myotomies, certain operations upon bones, and in hypodermic injections. The interstices between the muscular bundles are not of course so easily distended by a fluid as are those of the subcutaneous areolar tissue, but this is a matter of no importance in the injection of the few minims of liquid which are used in nearly all cases. Of course, when large quantities of fluid are used, as in the hypodermic administration of whiskey, etc., the loose areolar tissue immediately underneath the skin is to be chosen as the place for giving them, but under ordinary circumstances fifteen or even twenty minims of fluid can be forced into the substance of any of the muscles mentioned above without the least difficulty and with very little pain to the patient; moreover, when the deep muscular injection is made there is no necessity for the more or less careful and slow, and hence to sensitive patients, especially females, more or less painful insertion of the needle. The limb can be firmly grasped on its inner side, thus rendering the skin tense over the seat of the proposed puncture on its outer aspect, and the needle, if of proper length, introduced to its full length with a thrust so rapid as to be scarcely felt. Many a success or failure in the practice of medicine has been determined by a more trifling matter than the sensation of a nervous woman when receiving a hypodermic injection.

Next to morphia the drug most commonly used subcutaneously in my practice is ergot, prepared according to the following formula:

℞ Ergotin (Boujeau's)..... gr. xlviii.
Aq. rosæ.....
Glycerin.....āā ʒ j.

For over three years it has been my practice in every case of childbirth, where there were no contraindications, to inject five to twenty minims of the above solution deep into the substance of the gluteal muscles just as the head of the child escaped from the vulvæ, relying upon this measure, together with expression of the placenta by Credé's method and washing out the uterine cavity with very hot carbolated water in *every* case immediately after the delivery of the placenta, to secure firm, *unintermitting* uterine contraction, a guarantee against hemorrhage, possibly against after-pains, and probably against septic infection. With the latter end in view, the prevention of septic infection, the hot water used is carbolated, and as a further measure of safety during

the lying-in the vagina is very frequently irrigated with warm carbolated water until the lochial discharge ceases.

I was first led to give the hypodermic use of ergotin a trial in obstetrical cases by the perusal of an article by Dr. W. Allen Jamieson (*Practitioner*, October, 1877; *Braithwaite*, January, 1878), advocating its systematic use for the purpose of preventing after-pains.

Though in this respect it was not, in my hands, quite so productive of good results as Dr. Jamieson found it to be, still, its great usefulness in others, as mentioned above, soon attracted my attention.

Its chief advantage over the administration of ergot by the mouth is in the fact that its action is much more prompt, certain, and continuous, and that it can be given at a time when the termination of the labor can be definitely foreseen, *i.e.*, after the escape of the head, and produce its full effect when it is most needed, *i.e.*, after the delivery of the placenta, which action cannot by any means be predicated of any form of ergot administered *per orem*. Since early in 1878 I have thus used ergotine hypodermically in nearly all of quite a large series of obstetrical cases, and with only the happiest effects in all save one, in which, owing to the struggles and contortions of the half-chloroformed patient the injection was accidentally made into the subcutaneous areolar tissue, instead of deep into the muscles of the gluteal region, as was intended. The result was a large and painful cellulitis, terminating in an abscess, which was a long time in getting well.

All this may perhaps come under the head of "meddlesome midwifery," but it at least cannot be considered that "shilly-shally midwifery" which my teacher, the late lamented Dr. Budd, was wont, in his energetic way, to denounce as infinitely worse.

The formula for the above-mentioned solution of ergotin was published by S. Grose, Esq.. F.R.C.S., in the *Lancet* of November 17, 1877. It keeps perfectly well for a long time, while a watery solution alone does not.

It would be superfluous to mention the hypodermic use of brandy or whiskey to any one familiar with modern hospital practice, but there are, doubtless, many readers of this widely circulated journal who are not fully aware of the very great value of such medication in cases of impending death from collapse, especially when aided in its action by the simultaneous application to the epigastrium of a very hot spoon, or even a live coal.

On account of the large quantity of liquor which it is commonly necessary to use in these cases, two or three drachms to an ounce or more, the injection must of necessity be made into the loosely connected meshes of the subcutaneous areolar tissue, and abscesses must be expected sometimes to follow. In these desperate cases, however, if the patient lives till an abscess has time to form he is probably out of danger and ready to forgive the doctor for causing it.

Out of quite a number of such injections made by me in the last few years I can recall but two which were followed by abscesses. In one collapse occurred during the operation for excision of the hip-joint, and in the other heart-failure took place in an old woman nearly recovered from the effects of an overdose of opium by the use of atropia, electricity, etc. Both were broken-down patients, both recovered from the alarming condition for which the injections were given, but they had very extensive abscesses in the region of the needle-punctures.

I have tried ether hypodermically, but have not found it to possess any advantages over brandy or whiskey, used as above stated, in connection with heat to the epigastrium.

Without referring to many other remedies, such as atropia, camphorated oil, preparations of mercury, etc., which are often much better administered hypodermically than in any other way, I will bring to a close this communication, which has already extended far beyond the limits intended for it, by apologizing to those members of the profession to whom I have said nothing new. It is simply my desire to put the results of my own experience with a very important therapeutical measure at the disposal of those to whom perchance they may be of interest or service.

F. C. Ainsworth,
*Assistant Surgeon, U.S.A.*

Fort McIntosh, Texas, October 27, 1881.

## HOMŒOPATHIC CONSULTATIONS.

To the Editor of the Medical Record.

Sir: I am sorry Dr. Stair declines to define, for publication, the expressions, "homœopath" and "regular physician," and to indicate what he understands to be the "doctrines" of the former and of the latter. I think if any reader of this will take pencil and paper and thoughtfully endeavor to answer the questions for himself, he will not find the task an easy one; and if the answers of a dozen different gentlemen were compared, I feel confident that striking differences would appear. Until, however, I know just the meaning attached by Dr. S. to the expressions in question, I, of course, cannot discuss with him the issues involved. I am satisfied, nevertheless, that there is a great deal of misapprehension concerning this matter, and I crave the indulgence of a little space to present what appears to me to be the truth concerning it. The fact is that, for the past thirty-five years, physicians who are members of the American Medical Association, or of societies entitled to representation therein, have not been in the habit of consulting with physicians commonly known as "homœopaths." This is due partly to the fact that many, perhaps most, of the former have not wished to consult with the latter, and partly to the fact that it is generally supposed that the "Code of Ethics" expressly forbids such consultations; and the following clause from the Code is brought forward as evidence of this prohibition. The clause reads: "But no one can be considered as a regular practitioner or a fit associate in consultation whose practice is based on an exclusive dogma, to the rejection of the accumulated experience of the profession, and of the aids actually furnished by physiology, pathology, and organic chemistry."

Does this apply to the "homœopaths?" Do they practise according to an "exclusive dogma," and also reject the aids above referred to? If so, what is this "exclusive dogma"? I do not care to be told that it is the phrase "*similia similibus curantur*" (similars are *treated* by similars), which we often hear mistranslated into "like cures like," for this, correctly understood, is not a *dogma*, but simply a *proposition*, and one that excludes nothing. The Latin verb *curare* does not mean to *cure*, in the ordinary English sense of that term, but to *treat* or *take care of*, and is the equivalent of the French *soigner* and the German *behaudeln*. The word to cure, that is, to restore to health, would in Latin

be expressed by the verb *sanare*, in French by *guérir*, and in German by *heilen*. I assume, therefore, that, so far as homœopaths are concerned, the question of exclusive dogma falls; but even if it held, it would be necessary to show that, in addition, they rejected the "aids," etc., above mentioned before applying to them the rule of the Code. What is there, then, to prevent consultation with a homœopath? Nothing, so far as I can see, except the matter of personal inclination. Every regular may, if he chooses, consult with the average homœopath, without fear of the Code, and, if it is desirable to forbid such consultations, a new rule on the subject must be formulated, and one that will accurately cover the ground without loophole or way of escape. But is it desirable that such a rule or amendment to the Code be adopted? This is a question well worthy of consideration at the present time. Its discussion, however, should be preceded by a clear statement of the objections to homœopaths and to consulting with them. It is only by having a clear understanding of these points that we can arrive at a judicious settlement of the question as to the desirability of consulting, or of amending the Code so as to effectually prevent such consultations.

Respectfully yours,

ETHICS.

## ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from November* 13, 1881, *to November* 19, 1881.

McCLELLAN, ELY, Major and Surgeon. Having reported in person at these headquarters, will proceed to Fort McHenry, Md., and report to the Commanding Officer for duty. S. O. 204, Department of the East, November 17, 1881.

CARVALLO, C., Capt. and Asst. Surgeon. The leave of absence on surgeon's certificate of disability in S. O. 108, October 24, 1881, Department of the Platte, is extended five months on surgeon's certificate of disability. S. O. 256, A. G. O., November 12, 1881.

LAUDERDALE, J. V., Capt. and Asst. Surgeon. On discontinuance of McPherson Barracks, Atlanta, Ga., assigned to duty at Jackson Barracks, La.; to remain at McPherson Barracks until medical property, for which he is responsible, is disposed of. S. O. 124, Department of the South, November 10, 1881.

BYRNE, C. B., Capt. and Asst. Surgeon. Temporarily at McPherson Barracks, assigned to duty at Fort Barrancas, Fla. S. O. 124, C. S., Department of the South.

CUNNINGHAM, T. A., Capt. and Asst. Surgeon. Relieved from duty at Jackson Barracks, and assigned to duty at Mt. Vernon Barracks, Ala. S. O. 124, C. S., Department of the South.

COUES, ELLIOTT, Capt. and Asst. Surgeon. His resignation accepted by the President, to take effect this date. S. O. 260, A. G. O., November 17, 1881.

THE *Michigan Medcal News* complains that an item regarding the science and the smiles of infants was published in THE RECORD without acknowledgment. The item was seen in several journals, not all of them medical, and was credited to none in particular. We take pleasure now in giving the *News* its due.

ELECTRO-MASSAGE.—Referring to Dr. Butler's criticism, in a recent number of THE MEDICAL RECORD, Miss Post writes as follows:

"The word electro-massage, describing massage by the electrified hand, is to be found in the writings of Dr. J. Caldwell, of Baltimore. I extract from a description of the treatment of club-foot: 'We made daily alternating applications of galvanic and faradic currents.' . . . 'We ordered the limbs to be shampooed or massaged.' . . . 'The combined modes we have denominated electro-massage treatment' . . . 'In electro-massage the hand of the operator must be an electrode, so that each faulty, weakened muscle may be massaged and revitalized' (see *Gaillard's Medical Journal*, p. 269, 1881). The term was also used by me previous to its publication by Dr. Butler, having been printed upon my cards in August, 1879.

"The method of treatment is not new, but has been administered by manipulators under the name of manual electricity, etc. Drs. Beard and Rockwell make the following statement: 'There are those who, by long practice, are enabled, when necessary, to readily manipulate any portion of the body with either hand while there is passing through them a current so powerful as to keep many of the principal muscles of the arms in a state of contraction' (see 'Medical and Surgical Electricity,' p. 348, 1881).

"A monopoly cannot be sustained, even with regard to its mechanical production, as this also has been practised by Louis Sass and others of this city.

"Reference to the article in question, June 25th, p. 724, will show that I do not claim to have originated, but simply to have modified and applied. The essential peculiarity of the roller lies in the inclination of its handle thirty degrees from the vertical of the shaft, while the brush is distinguished by the extent of surface covered, and the consequent attenuation of the current at any given point. By its use we have rubefaction and stimulus to the skin without losing the general sedative effect of faradization by other means; if care be taken to avoid shock, the pulse will be slowed and the application will be followed by an inclination to sleep."

PEPSIN AS A SOLVENT FOR DIPHTHERITIC MEMBRANE.—A case is related by Dr. W. Hale White (*Lancet*) in which acid glycerin of pepsin was sprayed into the throat. The result was quite satisfactory, the pepsin seeming to soften and gelatinize the diphtheritic masses.

# Original Lectures.

## METHODS OF DIAGNOSIS IN DISEASES OF THE NERVOUS SYSTEM.

By E. C. SEGUIN, M.D.,

CLINICAL PROFESSOR OF DISEASES OF THE NERVOUS SYSTEM IN THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

### Lecture I.

*Gentlemen:* I propose to devote this and a subsequent lecture to a brief summary of the methods of diagnosis, more particularly those resorted to in organic nervous diseases, describing the instruments used and showing you how to go over a patient's body and examine it. A knowledge of the methods of diagnosis and of how much trustworthy information they will yield us is very important, and, I think, may be considered with profit. I will have a patient brought in, that I may make such manipulations upon him as are used in forming a diagnosis. Of the functions of the nervous system there are two general divisions: in the first place, the functions of movement; and in the second place, the functions of sensibility. An examination into the psychic functions is of great importance, but hardly a subject for a clinical discourse.

For determining the condition of the functions of movement there are three methods, viz.:

*First.*—By means of dynamometers.

*Second.*—By the performance of passive and active movements.

*Third.*—By inspection.

1. The instrument which is mostly used in making examinations into disorders of movement is the dynamometer, or strength-measuring instrument (see Fig. 1). There are several varieties of dynamometers. The one I use is the simplest kind, and consists of an elliptical steel spring which can be compressed in the hand or other parts of the body. Connected with it is a cog-wheel which moves an index-needle upon a dial, the index-needle remaining where it is carried by the muscular effort of the patient. The French instrument is provided with a double scale, which I think is altogether unnecessary. Observations made with this dynamometer, when recorded, should be accompanied with a statement as to whether the numbers refer to the inner or outer scale, as the numbers indicated on the two scales differ enormously. For instance, the dynamometer-needle in this patient's grasp points to 200 on the outer scale, and 70 on the inner scale. These numbers are supposed to represent kilogrammes, but I have no faith in the accuracy of such representations. Again, there is no advantage to be gained by knowing the exact number of pounds or kilogrammes of force exerted. A registration of degrees of force is entirely sufficient, and I always speak of the numbers indicated in any particular case as so many degrees. Now, as to the method of grasping the instrument. It should be grasped fairly and squarely in the hand, with the second phalanges resting upon the spring, and should be compressed without resting the hand or arm upon anything, and without giving the arm a swing at the moment of compression, as some patients will do. It is also important to place the face of the dial toward the palm of the hand, otherwise the fingers of the patient may interfere with the movement of the index-needle. We know that there is in most healthy individuals a difference in strength between the left and right hands, but we want to estimate it. There are very few healthy individuals with a difference of more than five or eight degrees; a difference of ten degrees would lead to the suspicion of paralytic weakness upon one side. Sometimes we find the left hand stronger than the right. A number of patients are left-handed, and therefore use the left hand more than the right. There are some occupations which tend to develop more strength in the left hand than in the right. Car-drivers show equal strength of both hands, or greater strength with the left hand, for the reason that the reins are held in it. I need not go into further details, but will say that you should be on the lookout for these normal variations in making tests with the dynamometer.

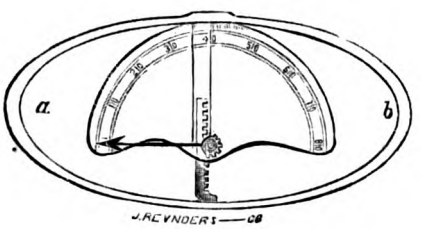

Fig. 1.

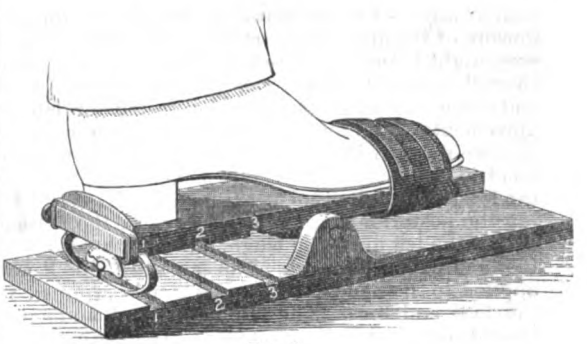

Fig. 2.

My friend, Dr. Birdsall has invented a foot-dynamometer, which is intended to record the comparative degrees of strength of either the anterior or posterior tibial group of muscles upon the two sides of the body. It consists (see Fig. 2) of a board with a movable foot-piece, which is grooved so as to receive the hand-dynamometer between the base-board and the movable foot-board. The foot-board is provided with a toe and heel strap, by means of which the foot is secured in position upon it. By placing the hand-dynamometer in the front grooves and strapping the heel down upon the foot-board and telling the patient to lift his heel, the strength of the posterior leg-muscles can be approximately estimated. For testing the anterior tibial group of muscles the ends of the instrument are reversed, the hand-dynamometer being left in position, and the toes strapped to the foot-board. The patient is then directed to attempt to raise his toes, and in so doing the power expended is transmitted through the heel to the hand-dynamometer. This instrument was brought to the notice of the profession in June last, by Dr. Birdsall, in a paper read before the American Neurological Association. Its accuracy is not

as great as that of the hand-dynamometer, but, as I have already remarked, we do not care so much for an accurate record of the force expended as we do for a comparative measurement of the force exerted on the two sides of the body.

There are registering dynamometers which record upon paper, or other prepared material, the muscular strength and tone of the patient. There are also dynamometers which will register the amount of pulling or pushing force exerted, and so on; but, for practical work, all that is necessary is a good hand-dynamometer.

2. Another method of testing disorders of movement is by handling the patient. The manipulations are made with our hands, and against the patient's will. We are thus enabled to determine the amount of resistance—strength of a great many muscular groups in the body. We lay hold of the patient's limb, having directed him to hold it in a given position, and tell him to resist our efforts at flexion or extension. By having the patient resist downward pressure upon the chin, we can determine whether there be paralysis of the masseters, temporals, or pterygoids. If paralysis exist, a very slight downward pressure will be sufficient to overcome the muscular resistance, and thus open the mouth. We can judge of the condition of the neck-muscles by the movements of the head. We direct the patient to hold his head perfectly stiff and upright, and see how much force is required to move it forward or backward. In a similar way we test the power of the flexors and extensors of the arm. In partial lead-paralysis only a very slight force is required to flex the hand. The short flexors of the hand can be tested in this way, and even the interossei can be tested by lateral movements of the fingers. With the lower extremities we proceed in a corresponding way. To test the quadriceps extensor femoris, we make the patient hold the leg in extension and attempt to flex it. For testing the posterior thigh-muscles we cause the patient to flex the leg upon the thigh, and take hold of the foot and pull it forward. The same test which was applied to the hands and fingers can be applied to the foot and toes. The abductors and adductors should be tested in the same way. In little children, under three years, the condition of the muscles may be examined by what I am in the habit of calling the cataleptoid test; or, more properly speaking, we note the absence or presence of the cataleptoid state in the muscles. I have found that if we divert the attention of a healthy baby and gently place one of its arms or legs in a given position, or in any position, that position will be maintained for several seconds or minutes. The limb is held by an automatic muscular contraction—an exaggeration of the muscular tonus. This normal state I call the cataleptoid state. In paresis or paralysis, more especially in infantile spinal paralysis, the affected limb, when most carefully placed as described above, falls at once, like lead, in obedience with gravity.

The ocular muscles can be tested by requesting the patient to follow an object about with his eyes without moving his head. Convergent and lateral movements can thus be studied. A good way of testing the interni is to hold your finger at about twelve inches from and in front of the patient's eyes, and move it gradually to within three inches. If affected, one eye or both eyes will diverge. We test the external recti muscles by making the patient follow an object in the outer fields of vision. It must not be assumed in obscure cases that this test is sufficient. There are cases of diplopia which are not revealed by this means. The method by which the oculists determine the existence of latent diplopia is to hold a strip of colored glass before one eye so as to color one of the images of the object, and thus enable the patient to distinguish them. Prisms are also used for detecting slight weakness of the recti muscles; but, as this is a part of a delicate manipulation of special eye practice, I need not more than refer to it.

3. The third method is by observing the patient's movements, or by inspection. The tongue is tested by requesting the patient to protrude it, and observing whether it deviates to the right or left, and how far it is protruded. You should guard against error in making the projection test. If the patient has lost a good many teeth upon one side, the tongue may be deviated in consequence, or it may be turned out of line by a cicatrix in itself. The tongue may be deviated by paralysis of one cheek. These sources of error are of considerable importance in a practical way. Facial paralysis on one side is evidenced by a drawing of the features to the opposite side, as well as by loss of expression on the affected side. In paralysis of the orbicularis palpebrarum the eye cannot be closed, etc. The various movements of the arm are to be tried in a systematic way. In evident paralysis, of course, we do not make these tests, but in slight cases we tell the patient to move both arms simultaneously, and note which one moves slower and less forcibly. I will show you a case of ordinary hemiplegia. I ask the patient to hold up both arms, but you see that the paralyzed arm does not go up like the other.

By voluntary movements we test the various forms of inco-ordination. We test co-ordination by testing the precision of the movements of the muscles, not their strength. A ready means of doing this for the arm is to request the patient to shut his eyes and try to put the tip of his forefinger upon the end of his nose. Some patients cannot do this. In that form of sclerosis known as disseminated cerebro-spinal sclerosis, and in posterior spinal sclerosis involving the cervical cord, the patient, upon being submitted to the above test, has oscillating movements of the arm and finger, and ends by thrusting his finger into his eyes or mouth. Similar oscillations are shown when the patient attempts to put a key in a key-hole. These resemble closely the movements of a person trying to do the same thing while in a state of acute alcoholic intoxication.

The movements of the legs and feet in walking have been the subject of much study. Some observers have endeavored to record the peculiarities of gait by means of giant sheets of paper so prepared that when a patient walks upon them imprints of his footsteps will be left. Such tests require considerable expenditure of time, and hence I would ask you to learn to judge of the gait of a patient by inspection and by the sense of hearing.

In the hemiplegic gait the foot is turned in, the heel raised, and the patient brings the extremity forward with a swinging, semicircular movement; he cannot bend the knee properly. This is what the French call the sickle walk. As the foot is brought forward, the outer portion of the sole of the shoe scrapes upon the floor. Hence it is that these patients first wear out the soles of their shoes upon the outer side. As a part of the hemiplegic gait should be noted the drooping shoulder of the affected side.

A characteristic walk is the ataxic. In this the leg is well raised, and the patient overdoes the ex-

tension and abduction movements of the step, bringing the foot down, heel first, in a jerking manner. A good method of testing co-ordination of the legs is by driving a pin into the toe of the patient's boot, and requesting him, while seated, to approximate the head of that pin to the head of another which you hold above it. If there be ataxia, the foot will oscillate in this movement, as the finger does in the nose-test. In the recumbent posture there is a more classical test of ataxia. Covering the patient's eyes, we bid him put his right heel upon his left patella. If he be ataxic, the heel wanders about in a vain attempt to hit the mark.

Another peculiar walk, which is of considerable frequency, is the paraplegic, the walk of partial paralysis. In chronic transverse myelitis the patient walks with a scuffling movement, dragging his toes upon the floor.

By closing your eyes and listening to the walk of two patients, one ataxic and the other paraplegic, you can tell them apart easily. The former makes a loud stamping sound with his heels; the latter scrapes the floor with his feet.

An important walk is the tetanoid, which I first described in 1873.* The patient takes very small steps and turns the toes inward. The feet are approximated, and there is a tendency to crossing of the legs from over-action of the adductors. The legs are rigid and the feet drag. You will find this in many children, occasionally in adults. This walk is believed to indicate primary or secondary sclerosis of the lateral columns, or want of development of the same parts.

In hysterical hemiplegia the walk is peculiar. A woman may seem to have complete paralysis of the arm and partial paralysis of one leg. In walking she moves the leg in the proper vertical line; there is no sickle movement; the foot is carried carefully and squarely over the ground, and is dragged. Dr. R. B. Todd,† of London, who was one of the most acute and skilful students of nervous diseases thirty years ago, first described this walk.

The walk of patients with cerebellar disease is usually badly denominated in the books. It is spoken of as ataxic, but there is nothing ataxic about it. If you were to test a patient with cerebellar disease as you would one with ataxia, by requesting him to shut his eyes and put the end of his forefinger upon the end of his nose, etc., he would have no difficulty in doing it. The walk of cerebellar disease is inco-ordinate, though not ataxic. It is more like the inco-ordination of intoxication, or, as the French writers call it, *titubating*. The patient tries to extend his base of support by separating his feet, and his body oscillates from side to side. If the feet be bare, the patient's toes will be seen working abnormally, and apparently digging into the carpet. Nothnagel‡ has written the best account of the cerebellar walk.

I will add a few words about reflexes. These are tested usually by pinching, burning, or tickling the soles of the feet and other parts of the body. The tendinous reflexes are of more recent discovery. We determine their existence or non-existence by tapping upon the tendons with the finger, as in percussion. Then, there are internal or visceral reflexes, such as those of the bladder resulting from the organ being filled with urine, those of the larynx, and so on. In most of our examinations we test the tendinous reflexes. The tendon-reflex can be tested anywhere that a tendon can be got at. Upon the leg you can tap the tendo Achillis. The most commonly used and most convenient place of testing the tendon-reflex is at the knee. If we tap upon the hamstring tendons we get a movement backward. The tendon of the quadriceps extensor femoris, or ligamentum patellæ is always an object of investigation, and striking it causes a partial extension of the leg. In certain spinal diseases no reflex movement is there present; in other conditions of the cord there is increased reflex at the knee. The best way of judging this is to use at first a minimum amount of force in tapping the tendon, increasing it as necessary to develop the reflex movement. Dr. Gray, of Brooklyn, made some interesting experiments three years ago, upon some of the students of the Long Island Hospital Medical College. as to the normal tendon reflex at the knee. He found it absent in two or three individuals out of a hundred healthy subjects; and I have seen similar exceptions.

*Disorders of sensibility.*—Here we come in contact with the consciousness of the patient—the ego of the patient, and we are, to a certain extent, at his mercy. In children this part of the diagnosis is limited to a very great degree on account of their inferior intelligence. For example, the sense of sight cannot be fully tested in these little patients, and when testing common sensibility we have to pinch and tickle them, and make use of other coarse tests. The special examination of the eyes and ears I will pass over for the present.

We will now consider the perception and localization of simple contact such as produced by the finger or a feather. The patient's eyes being closed, we touch him slightly in different parts, and ask him if he feels, and where he feels the contact.

The question of "muscular sense" is an involved one. Some believe that the muscles have no proper sensibility, and that we know our muscular movements by psychic estimation of the force employed, yet there are some persons who cannot feel a tap or

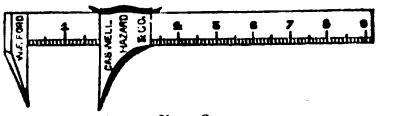

FIG. 3.

prick upon the skin of the leg, yet will feel firm pressure made upon the calf. There have been instruments devised for determining the amount of weight in grammes which a patient can distinguish. We test sensibility to pain in various ways. The use of the hot iron and matches I object to. We are not allowed, in an examination, to adopt such methods as will result in scars. A faradic wire brush is harmless, produces no scar, and is really more painful than cutting or burning, as I have repeatedly seen; and a clean, sharp needle is not objectionable.

The brothers Weber, of Leipsig, gave us forty years ago a form of æsthesiometer, which is much like a shoemaker's rule, with one end stationary (see Fig. 3). Another form of æsthesiometer is made like a compass, with or without a vernier (see Fig. 4). All æsthesiometers should have dull points. Dr. Birdsall has devised an improvement upon the former instrument. It consists in the attachment of a

* Description of a Peculiar Paraplegiform Affection. Archives of Scientific and Practical Medicine, No. 2. New York, February, 1873.

† Clinical Lectures on Paralysis, etc. London, 1856. p. 257.

‡ Topische Diagnostik der Gehirn-Krankheiten. Berlin, 1879, pp. 59–61.

point at one end of the instrument, so that a patient can be pricked at will. We know from Weber's researches the distance at which two points of the

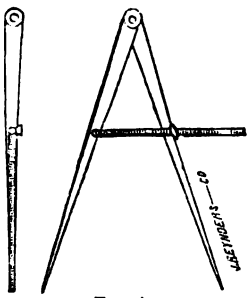

Fig. 4.

æsthesiometer can be distinguished on all the parts of the body. The following are some of the more important according to Valentin: *

| | Millimetres. |
|---|---|
| At the tip of the tongue | 1.00 |
| " palmar surface of tips of fingers | 1.50 |
| " " " " second phalanges | 3.24 |
| " " " " first phalanges | 3.44 |
| " dorsum of the tongue | 5.22 |
| " dorsal surface of fingers | 8.12 |
| " cheek | 9.46 |
| " back of hand | 14.50 |
| " skin of throat | 17.27 |
| " dorsum of foot | 26.10 |
| " front of sternum | 33.07 |
| " middle of back | 50.43 |

In estimating pathological conditions I am in the habit of making considerable allowance for normal variations. The points are to be applied to the surface of the skin simultaneously. This requires a certain degree of expertness on the part of an operator, and in order that the translation of the impressions be correct, some degree of intelligence on the part of the patient is required. In testing the tongue, the patient is to indicate the answer by holding up one or two fingers. With the thumb and forefinger you can increase or decrease the distance between the points.

One word about motor and sensory tests with a battery. For this purpose, either a faradic or galvanic current can be used. We use both currents for testing the condition of the connection between the nervous centres and the peripheral organs. I can only formulate a general law, and it is this: that in cases of disease of the brain in which the spinal cord and nerves continue to act upon the muscles, even though the will has no influence over them, the electrical reactions are preserved. In cases of certain spinal lesions, especially in transverse lesions, the same law holds true.

The affections of the spinal cord which destroy or involve the gray matter of the anterior horns will be accompanied, within a week or two weeks, by a loss of reaction in the paralyzed muscles and their nerves; whereas, with a lesion of the spinal cord which leaves a certain part of the gray matter below the lesion uninjured, even though it be but half an inch, we will get reactions in those muscles connected with the healthy part of the cord. In cases of injury to the spinal cord very low down, which destroy the lumbar enlargement, the muscles of the paralyzed legs undergo atrophy and lose their reaction to faradism. With a destructive lesion of the cervical enlargement, the same occurs in the hand and arm. The law may be stated in the following words: destructive lesions of the gray matter of the cord abolishes faradic reaction in the associated or dependent muscles. The same law is applicable to so-called peripheral paralysis, in which the nerve-trunk has been divided or crushed. Hence, you see there is nothing pathognomonic determined by means of the electrical test: it is of conditional value.

I would like to say something about the use of the ophthalmoscope. I consider its use of great importance in the study of nervous diseases; yet I feel that too much has recently been claimed for it. I would urge all of you to learn to use it and to recognize the healthy fundus. By so doing you will get negative information; and you should also learn to recognize atrophy of the optic nerve, neuro-retinitis, or choked disc, and the retinitis of Bright's disease. These signs are positive and valuable indications of disease. It has been claimed that by the ophthalmoscope we can determine the condition of the intracranial circulation, judging of this by the state of the retinal vessels. This I do not believe to be possible, partly because of the great normal variation in the circulation at the bottom of the eye; partly because the varying appearances of the vessels, according to the condition of the refraction of the eye; and lastly, because it is not at all certain that there is any correspondence between the retinal and cerebral circulations. I am supported in these statements by leading oculists, who consider it a delicate task to decide whether a retina be hyperæmic or anæmic.

* For a complete table in lines (about 2 mm.) consult Flint's Text-Book of Physiology, p. 753, New York, 1881.

---

New York Medical Students.—The number of medical students this year in New York is approximately, as follows:

College of Physicians and Surgeons, 473; University Medical College, 580; Bellevue Hospital Medical College, 415; Women's Medical College, about, 40; total 1,508. Besides this, there are about 90 veterinarians, and about 100 homœopathic and eclectic medical students, male and female.

We notice in the *Philadelphia Medical Times* that the University Medical College holds its own in numbers, despite the requirements of a preliminary examination. Jefferson Medical College, on the other hand has, according to the same authority, a diminished class.

It is gratifying to learn that the University Medical College of Philadelphia is succeeding well in the stand for higher education that it has taken; also to learn that the College of Physicians and Surgeons of this city, has every reason to be satisfied with the advance in requirements which it has adopted. It is to be hoped that New York will soon have a college that is on a level with what Boston and Philadelphia present to us.

Quacks in Illinois.—At the last meeting of the Illinois State Board of Health, it was stated that twenty-three practitioners had been compelled to leave the State because of inability to comply with the law. It was voted not to recognize diplomas coming from the College of Physicians and Surgeons at St. Joseph, Missouri.

## A DISSENTING VOICE FROM THE STANDPOINTS TAKEN BY D. W. BLISS, M.D.,

### In Regard to the Diagnosis, Prognosis, and Treatment of the Case of President Garfield.

By E. B. TURNIPSEED, M.D.,

COLUMBIA, S. C.

It is, perhaps, due the profession and the public that I should apologize for thus seemingly thrusting my opinions upon them at a time when the family of the late President is enshrouded in grief, and the distinguished surgeons in charge acknowledge their utter defeat in the surgical treatment. I falter when I think of the grave responsibility and my incapacity for so great a task, and console myself with the hope that it is only by discussing the important questions involved that truth can be reached and the ultimate advancement of the science of surgery promoted.

The whole question is, in a nut-shell: Is this modern surgery? Can all the resources of modern surgery do no more than was done for an unfortunate man shot down as poor President Garfield was? If this be true, we should invoke the manes of the great French surgeon, Velpeau, and cause to be echoed and re-echoed throughout this broad land his dying words to the young physicians who surrounded his bedside: "*Travaillez! Travaillez toujours!*"

*Diagnosis.*—Before probing the wound at all, the relative positions of the assailant and the assailed should have been accurately investigated, and, if possible, ascertained. This could have been immediately done, it seems, as Guiteau himself, in his confession, states: "I stood five or six feet behind him, right in the middle of the room, and in a diagonal direction from the President to the northwest."

Much has been said about the deflection of the ball. Doubtless, if an imaginary line had been drawn from the muzzle of Guiteau's pistol to the point beneath the pancreas, where the ball lodged, it would not have deviated much from the track the ball had made in the body of the President from its entrance to this point. But suppose it varied greatly. All military surgeons ought to know that, let a ball meet whatever obstructions it may in its transit through the body, it always will, after passing them, tend to resume its march in the line in which it leaves the muzzle of the gun or pistol. To illustrate: I have known soldiers on the battlefield to receive a ball in the forehead, pass around the head, and take its exit exactly opposite on the back of the head. I have more than once known soldiers to receive balls at some point of the sternum, opposite the union of a rib, pass around the body, following the rib, and make its exit exactly opposite on the back, making it appear that the man was shot through and through his chest.

I could give more evidence on this point, but do not think it necessary. Of course, when it penetrates bone the resistance may deflect it; but the amount of deflection is in inverse ratio to the power or force with which the projectile is sent, as well as the distance the assailant is from the assailed.

I think I can say it is an axiom in military surgery that, if you grant *sufficient force* to the projectile, it matters not what the resistance may be and what amount of deflection, it will resume the original line of march after passing the obstructions. Therefore, I conclude, when coupling the relative position of Guiteau to the President with the fact that the pains in his feet and legs indicated either injury to the spinal cord or shock of the spinal column, the surgeons would have been justified in locating the ball either in or to the left of the spinal column, and I have been reminded by citizens here that I then stated that to be my opinion.

It seems that Dr. Bliss made no effort, when first called to the President, to ascertain the relative position of Guiteau to the President at the time he received the shot, and this is evidenced by the direction in which he persistently probed for the track; and it seems, further, that his efforts may have resulted in making one or more false passages, as he says: "After withdrawing my finger I made an exploration with a long, flexible silver probe, which I suitably curved before entering, and gently passed it downward and forward and downward and backward, and in several directions." He does not say how far he introduced the probe, but the resistance to the small silver probes once entered between the muscles, or fascia and muscle, is so little that I know full well by experience very slight pressure will force them to their full length.

It appears, however, whether the probing did it or not, the pus burrowed just in the direction in which he probed. My impression is, had the doctor taken into consideration that the ball was fired in a diagonal direction from right to left, and had he used a probe of coiled steel slightly smaller than the track, pressing it gently but continuously to the left, as plainly indicated by the position Guiteau held relatively to the President, he would not have failed to have entered and followed up the direction of the track, and, with such an instrument as I will hereafter describe, could have reached and located the ball.

This instrument is yet unknown to the profession, and but for reasons—also hereafter given—would have been at his service.

It seems that the surgeons in attendance upon the President are consoled as regards the injury he might have sustained from the presence of the ball by asserting that they found, after the autopsy of the body, that it had become encysted. Ordinarily these balls give no serious trouble, but from time to time we meet with those that, although encysted for years, give *great trouble*. I remember a young prince, an aid on the staff of Count Osten Sacken during the siege of Sebastopol, who consulted me in regard to the propriety of removing a pistol-ball, lodged and encysted in the lumbar region, which caused him at times much pain and inconvenience in performing his duties. It had been received in a duel some eight years previously. I have now a case of encysted musket-ball, received during the late civil war, in the glutei muscles, to remove when located. He is a railroad man, and at times it incapacitates him for business.

These encysted balls that give trouble doubtless are located near the trunk of some nerve-sensation, or in the midst of a network of their sentient extremities.

As there was no loss of motion or sensation, it was evident that there was no permanent or serious injury to the spinal cord, but that the pains in his feet and legs were caused by the shock the spinal column had received, and I cannot conceive how the surgeons

consented to believe the ball did not reach the spinal column, and how they could be satisfied, with the knowledge of the position of the parties and the laws of motion as applied to missiles, that the ball was deflected from a diagonal to a straight line, and passed in this line of march the distance, perhaps, of eighteen inches, I will venture the opinion that no such thing ever did take place.

*Prognosis.*—President Garfield's case was not necessarily fatal. He naturally was a man of large, fine physique; never was dissipated; was in good health at the time of injury, and the promptness with which his system responded to all efforts used by his surgeons to bring about reaction were favorable, in the abstract, to the highest degree.

*Treatment.*—Of course, in my remarks I will confine myself to the surgical management of the case, and perhaps I cannot meet the inquiry of the profession at large better than just to answer the questions of Dr. Bliss that are pertinent to these points.

*First.*—Would the condition of the President, immediately after his injury, have justified a more thorough exploration of the wound, or would such a procedure have been safe at any time before primary reaction was established? He acknowledges in question fourth that reaction was comparatively complete on the 3d of July, and this, in my humble opinion, was all that was necessary to have accomplished what I will hereafter demonstrate could have been done—the removal of the ball and establishment of such drainage as would have relieved the track and neighboring parts of all pus, and thus have avoided septicæmia.

Questions second and third it is not necessary for me to answer. Of course the surgeons were the best judges in these matters. In question fourth he seems to attach much importance to the probable production of hemorrhage if the wound had been probed on the 3d of July, after reaction had taken place. Well, suppose it had! How could so small a track, as it then opened into no cavity, give exit to blood enough to kill such a powerful man? Would not the blood have coagulated all along the track after removing the instrument, and thus plugged up the bleeding vessels? And if the surgeons found there was too much bleeding, could they not have devised means to plug up with some foreign substance enough of the track to arrest the hemorrhage? Of the two evils, that of failing to locate the ball or encountering hemorrhage, which was the lesser?

*Fifth.*—In regard to delay for the consulting surgeons' arrival: if they had not the proper instruments, or were unwilling to assume the responsibility, and did not have the required help in Washington, then delay was justifiable; otherwise, not.

*Sixth.*—If the ball could not be located, of course it would have been unjustifiable and reckless surgery to cut in search of it.

*Seventh.*—As to the innocence of encysted balls, I have given my opinion above.

*Eighth.*—If ever the ball had been located any time during the President's illness, it would have been unjustifiable and hazardous to cut it out, either from the front or rear; but I firmly believe that my bullet-forceps would have followed the tortuous track, seized and brought out the bullet at the point of its entrance.

To the ninth question I would answer, that the dietetic treatment and nursing were superb; but in the surgery, omission of points, which, if observed, would have probably resulted in recovery.

*Tenth.*—The mistaken diagnosis, in my opinion, was not a natural result of the condition present, but in consequence of, first: not weighing the point of the relative position of Guiteau toward the President at the time of firing, which was undoubtedly diagonally toward his right, the ball making almost the same angle from right to left *after* penetrating the body that it did when passing through the air; and also the pain in the feet and limbs, which was an evidence of shock, at least to the spinal column.

*Eleventh.*—The surgical treatment should have been different, either with or without the knowledge of the locality of the ball.

I will now conclude my article by giving briefly my opinion of the surgical treatment, and describing, with two woodcuts, two instruments of my invention, one of which would have located the ball and indexed its depth from the surface of the body; while the other would have seized and brought it out by the channel of entrance.

I may be met at the threshold by Dr. Bliss with the assertion that no such instruments were then known to the profession, and I might have been induced, under different circumstances, to offer suggestions.

These instruments were invented before the dastardly attempt upon the life of the President, and I had no disposition to withhold them from any services they might render suffering humanity where the dignity of our noble profession was not compromised.

I will now first describe the probe or indicator (*vide* Fig. 2). Its total length, including the handle, is thirty-two inches; length of cylinder, twenty-three inches; diameter, three-sixteenths of an inch.

It is made of coiled or vertebrated flattened steel; the piston is made of cable-wire, with a needle eight inches long and about the size of an aspirator-needle at the extreme end. The whole apparatus is sufficiently flexible to pass any angle a bullet is likely to make. When the ball is reached the sensation of touch or rebound against the end of the cylinder will indicate it. Then the needle which is attached to the end of the wire is forced out at an opening in the end of the cylinder, and instead of going straight, describes the arc of a circle as it passes through the tissues intervening between the ball and the surface of the body. The scale on the handle of the piston nearest the operator being of the same length as the needle, marks the depth of the ball from the skin. Once the ball is found, the needle is used as a director in cutting down to it. The bullet-forceps or extractor (Fig. 1) is similarly constructed of coiled, flattened, or vertebrated steel of the finest material; the sheath is twenty-six inches, including handle; the cylinder alone, twenty-two inches; diameter, five-sixteenths of an inch; the piston is of cable wire, and at the end farthest from the operator are four wedge-shaped jaws, the length of a Minié ball, each jaw having on its inner surface, near the point, an inverted barb, similar to that of a fish-hook. The jaws are made to open and fold by means of a beautiful joint. Forceps that open with a hook at right angles to the jaw, such as those invented by the Messrs. George Tiemann & Co., can never seize a ball, as the soft parts would have to be forced asunder at that point in order to make room for the hooks to be imbedded in the lead; and if it were possible to seize or hook the ball at its very base, I am quite sure, with the force necessary to use the hooks, they would be broken or tear out their hold.

The wedge shape of my invention, I find, after

much study and experimenting, is the only one that will do at all, as they can be passed between the lead and soft parts in a ball of any size.

The inverted barbs are more firmly and deeply imbedded in the lead the greater the force used in traction.

I cannot conceive of any complications whatever

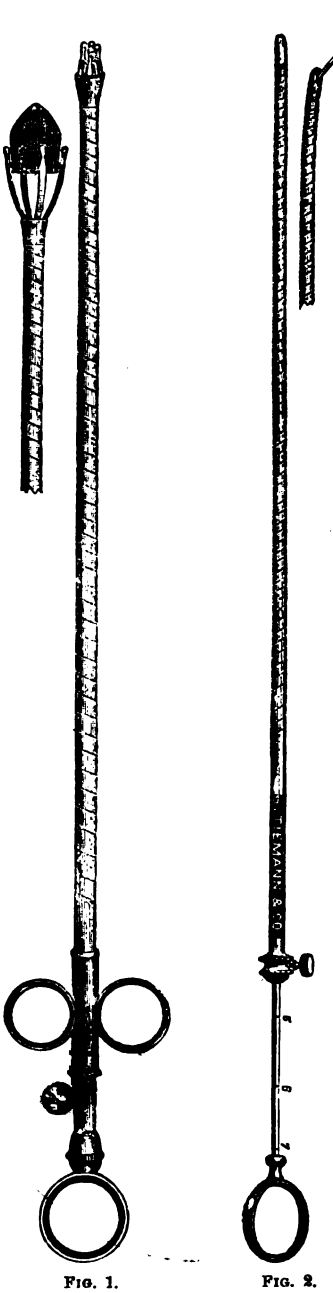

FIG. 1.

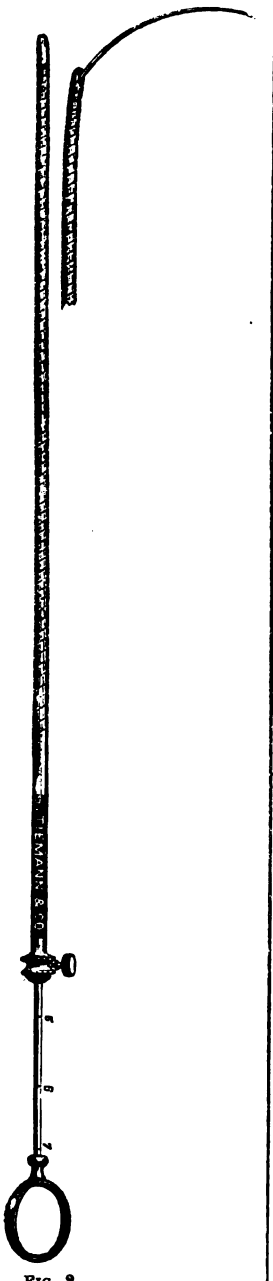

FIG. 2.

that would cause this instrument to fail in extracting any ball.

I firmly believe the instrument first described would have located the ball in President Garfield's case, the probing, of course, directed by a knowledge of the position of Guiteau to the President, as well as the injury sustained by the spinal column, which was indicated by the pains in the feet, etc.

And further, I believe the last-described instrument would have followed the tortuous course of the ball, and seized and brought it out at the line of entrance. Of course, we are all fallible, and I may be considered presumptuous by the profession; but I have a firm conviction that time and a full test of these instruments will prove the correctness of my assertions.

This instrument, with the piston removed and introduced from time to time, also with proper position of the patient—that of an inclined plane, feet and lower part of body elevated—would have given effectual drainage to the wound, and probably prevented septicæmia. To the Messrs. George Tiemann & Co. are due the thanks of myself and all who agree with me for the perfect working of this instrument.

This instrument can doubtless be effectually used to extract foreign substances from the air-passages, stomach, and bladder, as well as polypi from any of the cavities of the body.

*Autopsy.*—It would seem that the autopsy was unsatisfactory, as Professor Weisse, who made the report for publication of the surgico-anatomical study of the wound, by request of Dr. Bliss, indicates, when he says: "It is a matter of great regret that the autopsy was not made from the back instead of the anterior plane of the body."

The French method of making post-mortems I think preferable to the English, the one adopted.

It is not necessary to go over the lesions anatomically in detail. Suffice it to say that, although it is claimed that there was no communication between the large pus-sac—four by six inches—immediately under the peritoneum, and opposite posteriorly to the right lobe of the liver, and the track of the ball, yet may not the opening have been closed by adhesions during his long illness?

Further, I cannot understand how the bullet in its transit directly caused the aneurism, as the latter is ordinarily caused by the rupture of the internal coats of an artery. May it not have been caused, too, by sloughing, the effect of defective drainage, as it seems this part of the track was dilated by pus?

It may be inferred from what Professor Weisse says that the ball was not found "in situ," and therefore the cyst alone, torn, without the presence of the ball, would furnish unsatisfactory evidence in regard to its likelihood of giving no trouble. Also we are told that the large pus-sac under the liver was ruptured before its relative position to the bullet-track was ascertained.

*Conclusions.*—President Garfield's case, although an exceedingly doubtful one, was not necessarily a fatal one. My opinion is that, had the position of the parties been clearly determined, and the necessary importance attached to the pains, which presented themselves immediately, manifestly indicating injury, whether permanent or not, to the nervous centre; and had a large probe of coiled steel or vulcanized rubber, metal-tipped, been used, the direction of the ball-track would have been found. Once found, it could have been extracted through the same canal made by entrance by means of such instruments as presented in this paper; and, the bullet once removed, the position of the patient should have been that of an inclined plane—say forty degrees elevation of his feet and lower part of body—several hours during the twenty-four, which, with the occasional introduction of a catheter of coiled or vertebrated steel or vulcanized rubber, the whole track washed out daily with a solution of carbolic acid, five minims to an ounce of water, would have fur-

nished sufficient drainage for all pus-accumulations, and, if there were any shut sacs of pus, would have prevented their contents from burrowing in an opposite direction, probably forcing an opening into the bullet-track, or pointed where an opening could have been safely made with the knife.

The very healthy condition of the patient at the outset, and the great struggle made by his constitution for life, was clearly demonstrated by the bony union of one or more of the fractured ribs, and the effort at reparation revealed by the autopsy.

Some may ask what would have become of the fractured vertebræ and spiculæ of bone in the vicinity of the tracks at various points.

As a full answer would extend this article, already too long, I refer them to the literature of the profession, to be convinced of what nature, diet, medicines, and the knife have accomplished in wounds when the lesions were fully as grave.

October 29, 1881.

## A CONTRIBUTION TO THE RELATION OF URETHRAL STRICTURE TO SEXUAL DEBILITY.

By GEORGE M. SCHWEIG, M.D.,
NEW YORK.

Any contribution, be it ever so slight, to a subject that engages the daily attention of almost every physician, requires no apology. My object in reporting aphoristically the following three cases, is to direct the attention of the profession more strongly to the etiological relation that urethral stricture bears to the deterioration of sexual power. Cases of debility or complete impotency in the sexual sphere are so frequent, their mental, moral, and physical results so disastrous, that a recognition of the true etiology, and consequent possibility of proper treatment of each individual case, are matters of the highest importance both to physician and patient. Do not let me be understood to advance the theory that all cases of sexual decline are due to stricture, or, on the other hand, that all persons with stricture must necessarily, sooner or later, become impotent. I have, on the contrary, seen persons who had for years had multiple urethral stricture in the full possession of undiminished virile power. I must maintain, however, as the result of extended personal observation, that the two conditions very frequently coexist, the history of the respective cases, both before and after treatment, pointing to the stricture as the cause, the debility the effect, the resisting power of the spinal cord being a law for each individual case, and governing, generally speaking, the frequency of their occurrence. It is in such cases that the lesson taught by the following clinical report may aid in forestalling a long-continued useless treatment, detrimental both to the well-being of the patient and the reputation of his medical attendant. I have selected three what appear to me typical cases, the details of which will appear familiar to every physician as counterparts of some of his own.

Case I.—Mr. M ——, aged thirty years, merchant, single, applied to me for treatment in June, 1879. Had for several years been gradually losing sexual desire, without, however, losing the power of erection. At rare intervals, from an idea that it was necessary to his health, he indulged in sexual intercourse, which was invariably followed by headache and general prostration that continued throughout the next day. Had gonorrhœa some years previous, which was soon followed by the rational symptoms of stricture. Was under the care of two physicians in Germany (whence he had but just returned), one in Frankfort, the other in Hamburg. They had both passed bougies and sounds, without, however, obtaining any but palliative results. I found a stricture at five and one-fourth inches, admitting with difficulty a No. 16 fr. bougie. The radical removal of this stricture was at once begun, and completed in a short time. It was followed by a gradual and eventually complete recession of the phenomena above indicated. The patient, whom I saw very recently, has married, and enjoys normal health.

Case II.—Mr. J——, aged twenty-five years, musician, single, came to me January 8, 1881, with the following history: Was well until about eighteen months ago. Since then experienced gradual loss of erectile power. Within the last six months his condition had been rapidly becoming worse, until of late the erectile power had entirely gone. Had gonorrhœa four years ago. Complained of constant soreness, amounting at times to decided pain, in lumbo-sacral region of the back. Had a variety of treatment at the hands of Boston and New York physicians, without the slightest benefit. A physical examination revealed some tenderness on pressure of the lower vertebræ, also contracted meatus, admitting with difficulty a No. 17 fr. bulb. With this I could detect no stricture, nor were any of the rational signs of stricture present. For two months I endeavored, by means of internal medication, galvanization of the spine, faradization of the genitals and erector muscles, and the persistent use of the cold sound, to improve his condition, but without avail. In the absence of any signs of organic spinal or cerebral disease, and recollecting the gonorrhœa, I had very strong suspicions of stricture, and induced the patient to allow me to enlarge his meatus sufficiently to introduce a large-size bulb. On doing this, my expectations were fully realized. I found two strictures of large calibre, one at five and the other at six inches. Their radical removal, which was at once begun, was followed by no immediate change in his condition; but treatment similar to that which before the removal of the strictures was entirely barren of results, now served, in a period of about six weeks, to restore him to normal health.

Case III.—Mr. R——, aged forty, merchant, single, presented himself February 15, 1881, with the following history: Had syphilis, both primary and secondary, about twenty years ago; also, about the same period, had gonorrhœa. For the last eleven years his health has been good, until within a year, when a gradual decline of virile power began, which culminated a few months ago in its practical loss. When attempting coition there was either no erection at all, or one so imperfect as to be unserviceable. There was not a single rational symptom of stricture, and he was unwilling at the time to submit to an examination. I gave him the usual treatment, both medicinal and electrical, for a month without effecting any change. On March 17th he finally submitted to a urethral examination, which revealed two strictures, one at five and one-half, the other at six and one-fourth inches. His meatus being somewhat contracted—sufficiently so to form an impediment to the radical removal of the strictures—I informed him that it would be necessary to slightly enlarge this. It took him upward of two months to muster up courage to have this done, during which time I did not see him. Finally, on May 27th, he reappeared and submitted to the operation. The strict-

ures were soon disposed of, and I told him to do nothing further, but go to the seaside in the summer, which he did. He called again at the end of August, and said he was as bad as ever. I gave him a mild tonic and told him to have patience another month or two, when I expected he would find himself all right. This prognostication proved correct. On September 28th he called to tell me that within the last two weeks a rapid change for the better had taken place, until, as he had abundantly satisfied himself during the last week, his sexual power was completely restored. To quote his own words: "I have never been stronger in my life."

The above cases speak for themselves. The constant irritation of the urethra that accompanies stricture, the transmission of this through the terminal nerves to the spinal cord, the consequent gradual exhaustion of nerve-force and energy (spinal neurasthenia), that makes itself felt in one or more of the organs that draw their nerve-supply from the affected portion of the cord, are sufficient explanation, physiological as well as rational, of the train of morbid phenomena under consideration. Further corroboration of this may be found in the circumstance that the good results obtained in these cases by the cure of the strictures are never immediate, but appear to accrue from a gradual recuperation of the spinal cord, consequent to the removal of the irritation; the time required for this recuperation, as well as its degree, vary with individuals.

322 East Fifty-Second Street.

## PRIMARY EPITHELIOMA OF LARYNX BELOW VOCAL CORDS.—UNIQUE CASE.—BILATERAL PARALYSIS OF LARYNGEAL ABDUCTUS.—DEATH.

By D. BRYSON DELAVAN, M.D.,

NEW YORK.

Male, aged fifty-four; married; French; laborer. No history of rheumatism, syphilis, or intemperance. Three years before admission to New York Hospital first noticed that voice was becoming hoarse. Four months before admission this hoarseness increased rapidly; began to suffer also with cough and pain in chest, both of which became more and more severe. When first observed, patient appeared moderately well-nourished. Appetite fair; no marked debility There was complete aphonia. Complained chiefly of pain in chest and cough, the latter attended with slight mucoid expectoration, and much worse at night. Physical examination revealed wheezing sound in larynx, heard both in inspiration and expiration. No pain in larynx on pressure. Chest barrel-shaped; prolonged expiratory murmur heard all over it. Dry friction râles upon left side inferiorly. No œdema of extremities. Urine slightly albuminous, but contained no casts. *Laryngoscopic* examination showed thickening of the laryngeal mucous membrane—more marked in the right false cord, which projected nearly to the median line and partly covered right true cord. Respiratory movements of right side of larynx wanting. (Unilateral paralysis of abductor muscle.) Intense congestion of both true cords. Movements of left side of larynx apparently normal. Glottic opening sufficient for ordinary respiration. Nothing discovered in trachea. Three days after above observations the dyspnœa, slight at first, suddenly increased and patient showed symptoms of approaching cyanosis. Breathing became labored, especially in expiration. Respiration 33; pulse 130 and strong. Tracheotomy was performed as speedily as possible, and without difficulty, but œdema of the lungs supervened, and death resulted from failure of the heart's action within six hours of the operation.

*Autopsy.*—Body fairly nourished. Rigor mortis well marked. Slight œdema of both lower limbs.

*Thorax.*—Extensive old adhesions, both pericardial and pleuritic.

*Heart.*—Large and flabby. Muscular tissue pale and yellowish; left ventricle dilated; valves competent; patches of atheroma in mitral valve and in aorta.

*Lungs.*—Both very œdematous. Mucous membrane of bronchi much thickened; bronchial glands not very large; trachea and bronchi contained frothy mucus.

*Larynx.*—Two upper rings of trachea cut. (Tracheotomy.) Condition of mucous membrane in neighborhood good. Both vocal cords eroded and roughened, the true and false cords being fused together on both sides. Beneath right cord projected a growth about one-half an inch in diameter at its base and five-sixteenths of an inch thick, the surface of which was nodular and consistence firm. The position of this growth corresponded to the lower fifth of the right ala of the thyroid cartilage above, extending downward over the right segment of the cricoid and backward to the anterior and inner border of the right crico-arytenoid articulation. It was completely overhung by the right vocal cord, so that its presence could not have been recognized during life. Careful dissection of the right crico-arytenoid articulation showed that the articular surfaces of the joint were in an apparently normal condition. There was marked thickening of the fibrous structures surrounding the joint, however, and an erosion of the surface of the cartilage at the outer angle, corresponding to the insertion of the crico-arytenoideus muscle. In the abductors themselves no structural changes were observed.

At *pylorus* was a cluster of enlarged lymphatic glands, some of which were cheesy at their centre.

*Kidneys.*—Both small; surfaces granular; cortex much atrophied; some urates in pyramids.

*Liver.*—Increase of connective tissue everywhere.

All other organs normal.

*Microscopic* examination of a section taken from the centre of the laryngeal tumor revealed large openings in very young connective tissue, which were filled with flat epithelial cells. In some of these openings epithelial pearls were found.

The case presents several points of especial interest:

*First.*—Its great obscurity. There were no symptoms demonstrable which might not have been caused by a severe chronic laryngitis or by tubercular laryngitis, while the symptoms common to cancer of the larynx, with the exception of laryngeal stridor and cough upon lying down, were entirely wanting. There was no dysphagia; no reflex pain in the ears; no ulceration. No nodules were visible by laryngoscopic examination; and there was no enlargement of the cervical lymphatic glands.

*Second.*—Epithelioma originating in the locality described above is extremely rare. Of fifty-three cases of cancer observed by Morell Mackenzie, but one (variety not named), arising from the posterior broad surface of the cricoid cartilage, at all resembles it; while of seven cases reported by Cohen, and of eleven by Fauvel, there is not one. Von Ziems-

sen, who has collected fifty-seven cases of primary laryngeal epithelioma, says, "the seat of cancer is almost invariably the upper and middle portion of the laryngeal cavity." He, also, mentions no case in which it occurred below the cords.

*Third.*—The nature and extent of the paralysis caused by the tumor, and its influence upon the patient's life. The œdema of the lungs, which was the immediate cause of death, was the direct result, evidently, of stenosis of the larynx, and this stenosis must have been due to one of four causes: 1st, occlusion of the trachea by the tumor; 2d, œdema; 3d, anchylosis of the right crico-arytenoid articulation, complicated with œdema; 4th, bilateral paralysis of the abductors. Examination, both before and after death, failed to demonstrate that either of the first three causes were present to a sufficient degree to seriously impede respiration, nor had the unilateral paralysis of the abductors, which had existed for a considerable length of time, produced more than a slight degree of dyspnœa. From the suddenness with which urgent dyspnœa was developed, there can be no reasonable doubt but that it was caused by an extension of the paralysis to the opposite abductors, *i.e.*, to *bilateral* paralysis of the crico-arytenoidei postici, a condition which, in the present instance, can only be accounted for by the theory held by Dr. George Johnston, of London, and others.* The presence of the tumor was sufficient in itself to have caused irritation and paralysis of the nerve-filaments which supplied the *right* crico-arytenoideus posticus, while the paralysis of the left side was due, in the absence of any peripheral cause, to "an influence propagated through the afferent fibres of the compressed and irritated vagus to the nerve-centre, and thence through the efferent fibres of the other vagus to the muscles of that side."

*Fourth.*—The importance of the early performance of tracheotomy in paralysis of the abductors.

The larynx was exhibited at a regular meeting of the New York Pathological Society, and is now deposited in the Pathological Museum of the New York Hospital (specimen No. 1559).

---

SMALL-POX INCREASING.—Small-pox is said to be increasing in the city. The City Board of Health has sent a circular to all physicians, asking their co-operation in getting rid of it. There is also an increasing demand for vaccine points from suburban officials. Two thousand points were sent to Rochester this week, owing to an outbreak of small-pox there, and demands for virus have come from Jersey City, Rahway, Paterson, Buffalo, and Essex County, Conn. Small-pox has appeared along the Delaware Valley between Port Jervis and the Delaware Water Gap. The source of infection is supposed to be Italian laborers, who are working on a railway in Sussex County, N. J., as an Italian, stricken with the disease in its worst form, who came from a place near Deckertown, died in the Reception Hospital in this city last week. The State Board of Health contemplates the establishment of a vaccine farm in a neighboring county in this State. At present the animals from which the supply of virus for this city and the correspondents of the sanitary officials is taken, are on a small farm at Clifton, near Passaic, N. J.

# Reports of Hospitals.

## HOSPITAL NOTES.

### DOUBLE BODIED UTERUS—RETENTION OF MENSES—UTERO-ABDOMINAL FISTULA ESTABLISHED.

THE following case occurred in the service of Dr. T. G. Thomas, at the Woman's Hospital. The patient, a Frenchwoman, had been suffering for sixteen years from what was supposed to be a fibroid tumor of the uterus. At every menstrual epoch she was tortured with pains which almost drove her to insanity. She had been under the care of a Parisian physician for a number of years, but failed to obtain relief. When she came into the hospital the tumor had attained the size of a child's head. She had always menstruated through the vagina; the uterine cavity measured from two and one-half to three inches. Dr. Thomas declined to remove the growth, thinking that such procedure would cost the patient her life, in which opinion he was supported by his colleagues, Drs. Emmet and Hunter. The woman, however, persisting in having an operation performed, it was consequently determined to remove both ovaries. The tumor was cut down upon, and on examination gave obscure evidences of fluctuation. Upon tapping it with a trocar and canula, *three pints of menstrual blood*, looking like tar-water, *were drawn off*. The case proved to be one of uterus bicorporeus, the cavity of one of the bodies communicating with the vagina, that of the other being closed. For sixteen years she had been menstruating from both corpora; from one the blood escaped per vaginam, from the other it could only be removed by reabsorption; hence the increase in size of the latter body. Diagnosis before the operation was, of course, an impossibility. The corpus uteri, which had been the source of all the trouble, was then fastened to the walls of the abdomen in such a manner as to allow of injection and drainage of its cavity through the abdominal parietes, the canula being kept in place. After the operation the patient developed a low grade of septicæmia, but subsequently improved, menstruated, and is now doing well. In this case it would have been useless to remove only the ovary of the supernumerary body, inasmuch as the woman would nevertheless have menstruated from both corpora at each catamenial period. Dr. Thomas preferred the procedure adopted to that of removing the ovaries, because the former subjected the patient to less risks. Attention was drawn to the possibility of future insemination through the abdominal opening.

### LIGATURE OF THE COMMON CAROTID IN OSTEO-SARCOMA OF THE SUPERIOR MAXILLARY.

At the Mount Sinai Hospital, Dr. Wyeth tied the right common carotid artery in a case of osteo-sarcoma of the superior maxillary, in order to reduce the pain and diminish the suffering attendant upon throbbing in the orbits. Marked relief followed the operation.

### COMPOUND TINCTURE OF BENZOIN IN FACIAL ERYSIPELAS.

Dr. Bull has revived the above treatment with good success in the erysipelas pavilion at Bellevue. The affected parts are painted with the tincture once or twice a day. As an application to the face he re-

commends sheet lint dipped in hot lead and opium. Instead of poultices in erysipelas of the extremities, he uses oakum soaked in hot lead and opium, and covered with oiled silk. By this means the moisture of the limb is retained, and a soothing influence exerted over the part.

### TREATMENT OF MALARIAL CHILL.

At the Bellevue Hospital the following means are, among others, employed to prevent malarial chill:

1. The hypodermic injection of pilocarpine, gr. $\frac{1}{8}$.
2. The inhalation of gtt. v. of amyl nitrite every twenty to thirty minutes.
3. The administration of chloroform and whiskey, of each ʒ ss.

The excessive diarrhœa of typhoid is said to be remarkably controlled by the administration of gtt. xx. of turpentine every two to three hours.

### LARGE DOSES OF BROMIDE OF POTASSIUM.

The following case may be of interest, considered in connection with others mentioned in this journal, as illustrative of the effects of large doses of the bromides. The patient was a female, aged twenty-one years, suffering from hemichorea. Grs. 610 of potassium bromide were given in three days, viz.: on the first day, grs. 350; on the second, gr. 160; on the third, grs. 100. The movements were controlled, the heart's action was diminished, no bromide rash appeared. The patient suddenly developed delirium, which continued after the bromide was stopped. Subsequently she became apathetic and semi-idiotic.

### TREATMENT OF FRACTURE OF THE PATELLA BY THE WEIGHT AND PULLEY.

At the Presbyterian Hospital there are two cases of fracture of the patella under the care of Dr. Geo. F. Shrady, which are being treated by the weight and pulley. Both fractures are transverse, were occasioned, as usual, by muscular violence, and the fragments were separated three-fourths and one and one-fourth inch respectively. The limbs are elevated on a single inclined plane, and two strong, broad bands of adhesive plaster are applied diagonally to the anterior portion of the thigh, crossing each other just above the patella, and embracing a pad at the upper margin of the upper fragment. These bands terminate in loops on each side of the leg, and are attached to stout cords which pass to a foot-piece and over a pulley to the weights. The lower fragment is merely fixed by a bandage passed around the splint. Extension is made over the entire region of the quadriceps muscle, while the pad applies itself over the upper edge of the upper fragment, bringing it in apposition to the lower fragment. By these means the fragments are maintained in perfect apposition, without discomfort to the patient. Dr. Shrady prefers this method of treatment to any other he has employed.

---

Orchitis of Mumps is not a metastasis, but a complication that can be watched for. It occurs only after puberty, and comes on between the seventh and ninth day generally. Its approach is indicated by a rise of temperature which occurs before any pain is felt. By keeping the patient in bed, taking the temperature, and at once applying hot poultices to the testicles as soon as fever appears, the symptoms are greatly mitigated.—Dr. C. Dulges, in *Lancet*.

## Progress of Medical Science.

Etiology of Uræmia.—Astaschewsky has performed a series of experiments on dogs, in which, after tying both ureters, he injected into the femoral vein, on different occasions, large quantities of urine, urea, creatinin, etc. He concludes that urea plays no rôle in the development of uræmia; that creatinin produces only doubtful effects; but that the inorganic constituents of the urine, when injected into the circulation in sufficient amount, give rise to symptoms closely resembling those of uræmia, and often produce a rapidly fatal result. From this it would seem to be apparent that very great importance is to be attached to the insufficient excretion of the inorganic constituents of the urine, particularly the salts of potash, in patients affected with Bright's disease, and that uræmia is essentially a self-poisoning of the system with inorganic substances.—*Allgemeine med. Central-Zeitung*, July 27, 1881.

Significance of Fat in the Urine.—Rassman divides the affections in the course of which fat is found in the urine into three classes: 1st, true chyluria, parasitic, and non-parasitic—in these cases the urine also usually contains albumen, and not infrequently fibrin; 2d, fatty degeneration at some point of the urine-forming or urine-conducting apparatus—to this class belong also those cases where the pus of an old abscess finds its way into the urinary passages; 3d, numerous constitutional affections associated with marked cachexia or dependent on systemic intoxication, such as phthisis, long-continued suppuration, pyæmia, yellow fever, poisoning by phosphorus or carbonic oxide gas, chronic poisoning by turpentine, and severe injuries of the bones. In these cases the blood contains an abnormal amount of fat, which passes off by the kidneys. As a proof of the correctness of this theory, Rassman cites the results noted in a series of experiments performed on dogs, cats, rabbits, and frogs. After injections of oily emulsions into the blood or peritoneal cavity, fat was usually demonstrable in the urine on microscopic examination. At the same time the animals became more or less somnolent, the blood-pressure sank for a time, and the pulse became less frequent. When large doses were injected, death ensued in a short time, the heart becoming arrested in the state of diastole. Similar results were obtained after injections of emulsified oleic acid and oleate of soda in one to ten per cent. solutions. Rassman thinks with Olshausen that these phenomena furnish an explanation of the retardation of the pulse usually noted during the first few days following childbirth; in other words, the retardation is due to fatty degeneration of the uterus and abundant absorption of fat into the blood.—*Allgemeine med. Central-Zeitung*, August 3, 1881.

Nervous Gastralgia Treated by Galvanism.—Vizioli narrates the history of a woman, thirty-five years old, who had been bitten ten years previously by a supposed mad dog. The patient was at first intensely excited, but became calmer after a few days, though she lost her appetite and strength, menstruation ceased, the senses of hearing and smell became abnormally acute, and paroxysmal attacks of intestinal colic set in. The latter became more and more frequent, and so violent as to cause the patient

to shriek with pain, sometimes causing fainting-fits or violent tonic and clonic convulsions. For the relief of the gastralgia, cauterization of the cervix uteri was practised. At this stage, when the affection had existed for more than ten years, Vizioli began to treat the patient with the constant current of twenty-four to thirty-six cells, placing one pole over the stomach. The sittings were given every other day. Amelioration was rapid; after the twentieth sitting the paroxysms ceased altogether, though there were faint reminders when the uterus was cauterized. The cauterizations, however, were continued, with galvanism.—*Med.-Chirurg. Rundschau*, August, 1881.

Treatment of Hydrocele in Children.—Defert's method of obtaining a radical cure in ordinary hydrocele, as published in the *Gaz. des Hôpit.*, 1881, No. 6, consists in evacuating the greater part of the contents of the sac through a trocar, and then introducing, through the latter, a director coated with melted nitrate of silver, with which he touches numerous points on the internal surface of the tunica vaginalis. A certain amount of the nitrate also dissolves in the residual fluid and mildly cauterizes the whole of the internal surface of the sac. The director and canula are then withdrawn. The director is charged by depositing powdered nitrate of silver in the end of the groove for a distance of 2 ctm., and melting it slowly over the flame of an alcohol-lamp in such a way that the caustic shall project slightly beyond the surface and tip of the director.—*Med.-Chirurg. Rundschau*, August, 1881.

Trephining the Ilium in Psoas Abscess.—In some cases of psoas abscess, after an incision has been made in the neighborhood of Poupart's ligament, the discharge of pus is more or less obstructed when patients occupy the horizontal posture. In these cases, when fluctuation can be felt in the loin, or when a probe passed through the incision in a backward and upward direction can be distinctly felt in the lumbar region, it is recommended to make a counter-opening in this situation. Where, however, neither fluctuation nor the tip of the probe can be felt in the loin, Fischer recommends trephining the ilium, and has practised the procedure in one instance. The patient, a man of twenty-four years, had a large psoas abscess on the left side, which had perforated into the hip-joint. After an incision in the groin, under antiseptic precautions, a large amount of pus was evacuated. The discharge continued quite free, but the abscess never seemed to empty itself completely, and fever not subsiding entirely, it was deemed advisable to make a counter-opening in the flange of the ilium. The patient's great emaciation enabled the operation to be performed easily; after incising the soft parts and tying a branch of the superior gluteal artery, a hole ½ ctm. in diameter was cut through the ilium, and quite a quantity of pus evacuated. The discharge continued to flow freely through this opening, none passing out of the incision in the groin. Later a drainage-tube was introduced through the second opening. For a while the patient improved, but a bedsore formed over the sacrum, infiltration in the apex of the right lung made rapid progress, and, after several months, death occurred from exhaustion. Post-mortem examination revealed extensive tuberculosis of the lungs, with caries of the ninth, tenth, and eleventh dorsal vertebræ, and disorganization of the left hip-joint; a small fistulous track remained as residua of the previously existing extensive abscess-cavity. Fischer thinks that the counter-opening in the ilium with subsequent drainage did all that could be expected of it, and that the operation is entirely justified under similar conditions. So far as he knows, it is the first time it was ever performed with this object in view, and he therefore recommends it for further trial. *Med.-Chirurg. Rundschau*, August, 1881.

New Method of Compulsory Alimentation.—When insane patients refuse to take food, Keppelmayer advises the following: the patient, being placed on a perfectly horizontal couch without pillow, one nurse holds the head, another the outstretched arms, and a third the legs. A soft-rubber Jacques' catheter No. 10, with a large lateral opening near the tip, is well oiled, introduced through one nostril, and slowly and gently pushed onward as far as the pharynx. Here it usually meets with an obstruction. Without using any force, very gentle pressure is now exerted until an act of deglutition is excited, by which the catheter is propelled into the stomach. These catheters are of such a length that, when the tip has entered the cardiac orifice, the other end hangs from four to six centimetres outside of the nostrils. A hard-rubber canula having now been fixed in the projecting extremity, a syringe with a capacity of about half a litre, and filled with fluid food, is fastened to the canula and the contents slowly injected into the stomach, after which the apparatus is withdrawn. Should the manipulator lose patience when the catheter is obstructed at the entrance of the pharynx, and use undue force, the tip of the instrument is liable to deviate from the proper course, and suddenly makes its appearance between the teeth. This manœuvre once acquired by a patient, subsequent attempts at catheterization will require particular patience and care, in order to succeed. The chief recommendations of this method of forced alimentation are its simplicity and the impossibility of causing an injury during its execution. Keppelmayer also recommends the employment of large-sized soft rubber catheters, provided with a large, smooth opening at the tip, for administering enemata.—*Med.-Chirurg. Rundschau*, August, 1881.

Observations on the Nephritic Affections that Complicate Pregnancy.—Leyden (*Zeitschrift f. klin. Med.*, Bd. II., Heft 1) recognizes four different classes of kidney affections during pregnancy: 1st. A form incident to and resulting from the peculiar circulatory conditions of the gravid state, so-called "Schwangerschaftsniere." It affects a previously healthy kidney, is not a true inflammation, and consists, anatomically, of fatty degeneration and anæmia of the swollen cortical substance, bearing some resemblance to the second stage of typical nephritis. The clinical features are a scanty secretion of urine, containing a large amount of albumen, and but few formed elements in the sediment. The affection is readily susceptible of complete restitution, albuminuria disappearing a few days after parturition. 2d. Nephritis *ex graviditate s. ex puerperis* — an acute nephritis, characterized by the presence in the urine of a copious sediment, numerous blood-corpuscles, casts, and epithelia. 3d. Pyelonephritis occurs infrequently. The urine contains a large amount of blood and pus-corpuscles, casts, and albumen. These patients complain of backache. 4th. Ordinary acute or chronic nephritis, not dependent on, but simply coexistent with pregnancy. Here œdema usually appears early. The sediment closely resembles that found in the first class of cases, but its characters are more sharply defined; more fat

granule-corpuscles are present, with tough, hard, and glossy casts. It is important to determine whether renal disease has existed before the inception of pregnancy, because, in this event, the disease usually becomes aggravated after parturition, while, as previously stated, the simple "kidney of pregnancy" usually tends to quick recovery.—*St. Petersburger med. Wochenschrift*, September 3, 1881.

INSANITY RESULTING FROM SYPHILIS.—M. Ball has given a *résumé* of Fournier's views on insanity attending syphilis, which, according to that observer, presents itself either as syphilitic dementia, as mania, or as general pseudo-paralysis.

In syphilitic dementia, the patient's temperament undergoes a radical change. His intelligence is clouded and his conduct strange. He becomes moody and taciturn. Labor is fatiguing and intolerable. His memory fails, though judgment often remains. Loss of memory may be either sudden and complete, or gradual and imperfect. The patient becomes careless as to his personal appearance, and very irritable. This condition may be designated as a precocious senility of the mind, differing from senile dementia, however, in being curable.

Syphilitic mania may be suddenly developed or present prodromal symptoms. The latter, when present, consist in a peculiar excitement, feverish activity, and in unusual loquacity. These prodromata terminate in delirium, which may manifest itself in several forms. Sometimes it is active and attended by complete insomnia. The patient becomes destructive, and suicidal tendencies show themselves. The delirium assumes the form of hypochondriasis or syphiliphobia. The patient believes himself persecuted. The delirium is impulsive.

General syphilitic paralysis. This variety of the disease begins with mental hebetude and with incoherencies of speech. The speech may become embarrassed, and stuttering, due to local paralysis, appears. Other partial paralyses, particularly those of the eye, soon follow. The diagnosis is based upon the concomitant symptoms, as headache, alopecia, and gummata, but particularly upon partial paralyses. Strabismus is another valuable diagnostic symptom.

The prognosis is favorable if the case receive prompt treatment, although the disease sometimes terminates fatally. The treatment must be energetic and thorough. At the beginning the mixed treatment is indicated: 5 grms. (75 gr.), at least, of the iodide of potassium should be exhibited daily, and inunctions also employed. If mercury is not well tolerated, recourse may be had to the chloride of gold.—*Annales et Bulletin de la Société de Médecine de Gand*, July, 1881.

A NEW THERMOGRAPH.—Marey announces that he has invented an instrument for the purpose of registering, simultaneously, the variations in animal temperature at two points in the body. The instrument consists of a diminutive Bourdon tube, which is placed in contact with the liquid of a thermometer, and which changes its curve in accordance with the degree of expansion of the liquid in the thermometer. The latter consists of a cylindrical brass reservoir, 6 mm. in diameter and 3 ctm. long. The tube of the thermometer terminates in a capillary tube of copper, which, in turn, opens into the Bourdon tube. The whole apparatus is filled with oil and then closed. The oil expands or contracts under the influence of variations in temperature, and in so doing changes the curve of the Bourdon tube, thus moving the index of a dial attached to the latter. Two of the thermographs just described enable the observer to obtain the respective temperatures of a deep and superficial part, at will. The registering dials are connected by flexible copper wire to the bulbs of the thermometers, and the latter may be placed at any point desired. Simultaneous registration of the deep and superficial temperatures shows that, in vaso-motor disturbances, exactly contrary changes occur in the temperature of central and peripheral parts of the body. In the case of vaso-motor spasm, the periphery is refrigerated and the central parts superheated. On the other hand, vaso-motor paralysis augments the heat of the surface, and cools the interior of the body. In some cases there is a parallelism between the temperatures of deep and superficial structures. Thus, inanition refrigerates, simultaneously, both central and superficial parts, while some diseases augment the temperature of the entire organism.—*Annales et Bulletin de la Société de Médecine de Gand*, July, 1881.

BROMIDE OF POTASSIUM, IODIDE OF POTASSIUM, AND CHLORAL HYDRATE IN THE TREATMENT OF CARDIAC DISEASES.—The views of several recent observers concerning the use of these drugs in heart diseases are collated by Dr. de Renzi.

According to Gubler, the bromide of potassium exerts a remarkable sedative influence upon hearts which are the seat of organic disease. It particularly diminishes their tendency to intermittent action. Dujardin-Beaumetz classes the bromide with the cardiac tonics, and regards it as inferior only in this particular to digitalis. Lee employs the bromide to fulfil the same indication. Renzi attributes the beneficial influence of bromides upon cardiac affections to its sedative and hypnotic effects.

Professors Lee and Renzi strongly recommend the iodide of potassium for cardiac dyspnœa, particularly when referable to parenchymatous rather than to valvular lesions.

Chloral hydrate is used to diminish the frequency and force of the heart's action, but does not lessen cardiac dyspnœa, and must be used with caution, lest it produce deep and persistent somnolency.—*Archives Médicales Belges*, July, 1881.

SANGUINEOUS TUMOR OF THE RIGHT VOCAL CORD.—Dr. G. Coupard publishes, in the *Revue Mensuelle de Laryngologie, d'Otologie et de Rhinologie*, July 1, 1881, a rare case of sanguineous laryngeal tumor. The patient noticed a change in his voice a year before applying for treatment. The difficulty of speech became gradually more marked during a period of six months, and then remained stationary. The patient had always enjoyed good health, and had experienced no pain in the larynx. He had suffered from granular pharyngitis. On laryngoscopic examination the epiglottis was found hyperæmic. The true vocal cords were reddened and had lost their normal polish. A bilobate polypus, without a pedicle and of a bright red color, occupied the middle third of the right inferior vocal cord. It was 8 mm. in length and 6 mm. broad. The polypus was removed by means of the forceps, and four applications of zinc chloride restored the cords to their natural color, and the voice to its former purity.

---

NERVE-STRETCHING has been abandoned by Billroth after a fair trial. It does not seem to be making a favorable impression in Vienna.

## THE TRIAL OF GUITEAU.

SEVERAL weeks ago we presented to our readers the question of Guiteau's insanity. We stated the view of his mental condition, taken by those who believe him insane, and gave the evidence both for and against such a position. Our conclusion, drawn from the facts then at hand, was that he could not justly be pronounced an insane and irresponsible man.

It is a truism, at the present day, to say that between perfect sanity and mania, humanity presents every shade of gradation. From the standard of perfect mental equipoise the mind passes through the different phases of nervousness, eccentricity, narrow genius, criminality, monomania, until we see its entire overthrow in the maniac.

Exactly what place on this line one should fix as the boundary between sanity and insanity no one can tell. It is an arbitrary point depending upon the special character of the expert as well as upon the acts of the alleged insane individual. It follows that in doubtful cases it is in the last degree unwise and unscientific for any one arrogantly to assert the certainty of his own peculiar views. The expert may defend his own position, but may not attack that of others.

Acting under such considerations as the above, we aimed in our previous remarks as much to present the evidence on each side as to make a special plea for either position. Still, a candid survey of Guiteau's history led us, as we believe it has most of our readers, to the belief that the assassin was not an irresponsible lunatic.

We confess that nothing has been brought out since our previous writing which would justify us in changing this position.

The chief additional evidence for the defence consists in brief as follows: The prisoner is alleged, some years ago, suddenly and without reason, to have brandished an axe at his sister and threatened her life. About five years ago, Dr. J. A. Rice, of Merton, Wisconsin, examined Guiteau as to his mental condition. His conclusion was that the prisoner was insane, this opinion being based on the supposed fact of hereditary tendency, the presence of moral defects, and of emotional exaltations. Dr. Rice found no delusions, however. He knew and attended Guiteau's father, but did not think him insane. Further testimony for the defence has been mainly for the purpose of substantiating the various eccentricities or incoherencies developed by the prisoner. That showing the illogical character of his lectures, and his occasional spontaneous outbursts of emotion, deserves the most attention. Testimony from one relative was to the effect that he was sincere, gentle, and humane. On the whole the defence would make him out a man whose moderate intellect was overmastered by vanity and intense religious fanaticism; and whose moral sense was markedly and congenitally deficient. The diagnosis, hesitatingly made, five years ago, was emotional insanity; now it seems to be delusional insanity.

Coming to the other side of the question, we find ourselves writing at a time when everything possible in favor of the prisoner's insanity is being brought forward. We cannot, therefore, in advance of the facts to be educed by the prosecution, attempt to present its side in any completeness. But there are some things which may be referred to as of importance in estimating the value of the testimony for the defence.

The question with medical men is whether Guiteau should be put with the insane or with that class known variously as the eccentric, the "crazy," or the "insane neurotic." This class of human beings inhabits the border-land of insanity, and its characteristics are described more or less fully by almost all writers on psychological medicine.

The eccentrics have generally some hereditary taint. They have no true delusions, though they often consider themselves persecuted or ill-used. Their judgment is weak; their ideas sometimes incoherent; their emotions are perverted and may turn themselves into some special channel, "perhaps into the fanatical adoption of extreme religious opinions and practices" (Maudsley). They may be vain and egotistical. The moral sense is blunted; untruthfulness and hypocrisy are often displayed. Their conduct is wayward, fickle, and perverse. In fine, the "insane neurotic" has, as a rule, a moderate amount of intellect, a weak will, and a perverted or exaggerated activity of the emotional nature (Bucknill and Tuke). He may have many of the physical characters of the insane: the unsymmetrical head, the shrivelled ear, at times the peculiar animal look (Wynter), and also the unequal pupil, referred to erroneously by Dr. Rice as an evidence of Guiteau's insanity.

It requires no straining to place Guiteau, so far as his past history goes, in the above category.

Such a person, in a life of forty years, must inevitably have done things which might be looked upon by some as insane. Yet the testimony of those who have known him most in his mature years, viz., his wife, his brother, Noyes, and others shows that they saw in him only something disagreeable and eccentric. He was indeed suspected of insanity by Mr. Scoville, but it may be that this was largely because he was such a nuisance.

It is an important fact also that though he had occasionally what would popularly be called delusions, yet none of them were sufficiently outrageous to be considered characteristic of insanity. And, further, in estimating this phase of Guiteau's character, one must remember that conduct or ideas are not insane simply because they vary greatly from the common standard. They must also vary from the standard which the education and training of the individual has set up as normal for him. The savage paints his body, but is not mad. A person is brought up to believe in spirits, or the Mormon bible, or the utility of thieving, but he is not on this account insane. Guiteau's peculiar education and associations are to be considered in estimating the absolute eccentricity of his ideas.

We have but a short space in which to refer to the final act of the assassin and its bearing on the case.

The insane neurotic does not by any means always become insane. If he does, it is oftener with some emotional explosion, which surprises its subject (Krafft-Ebung). Homicidal mania is generally characterized by its paroxysmal nature. There is no long-matured scheme beforehand, and no plan for escape afterward. We might fairly presume, from previous knowledge, therefore, that the killing of President Garfield was not the evidence of a final breakdown of Guiteau's mind.

One must decide on this, also, however, by a study of his conduct and apparent motives. We stated, in discussing the subject before, that there did not seem to be malice. From the facts presented by the prosecution since then, however, it seems not improbable that disappointment and desire for revenge had something to do with the act. We must add to this a vicious craving for notoriety. The driving impulse of a delusion that he was only an agent of the Deity cannot yet be held as of very great weight. It seems to have expanded since the murder, as a happy and useful after-thought. Guiteau was under no uncontrollable impulse, for he restrained himself from shooting once, when he "saw the pale face of Mrs. Garfield." He had designed a plan for escape; he did not trust to the Deity for that; he does not trust to Him now to save him from the mob as he goes to and from his jail. A madman is more consistent in his delusion.

Shall we say then that an act carefully planned, done with deliberation by a person who could restrain himself once, by a person who was actuated partly, perhaps, by a delusion, but also, and perhaps more largely, by a passion for notoriety, and by feelings of disappointment, resentment, and revenge—is that of an irresponsible lunatic? Can society afford to let such men as Guiteau go unpunished?

Laying aside names, this last is really the essential question: Is Guiteau, call his mental crookedness what one pleases, irresponsible?

But this we cannot discuss at present.

---

### FURTHER PROGRESS IN THE SANITARY SUPERVISION OF PUBLIC SCHOOLS.

At a meeting of the Cleveland Board of Education, last month, Mr. A. W. Fenton made a further report upon the subject of the public schools.

The results of the investigations into the health of the pupils in these schools were given by us, several weeks ago. The facts thus obtained were novel and striking. They demonstrated with unusual force the need of a careful sanitary supervision. Mr. Fenton, after dwelling upon this investigation, gave a long series of quotations from eminent medical authorities regarding the subject in hand. These quotations represented the opinions of the various gentlemen, communicated to Mr. Fenton in response to his personal inquiries.

Thus, from Philadelphia, Dr. William Goodell writes:

"The brain-cramming of our boarding-schools and public schools, their buckram proprieties, autocratic Bismarckism of their government, breed a host of sickly girls, who swarm in every class of society. Manifold diseases, functional and structural, date from the recitation-room," and further, "the physical education of our girls is sadly neglected. Female scholarship nowadays means invalidship!"

Drs. S. Weir Mitchell and S. D. Risley write in the same vein. From New York City, Drs. M. Putnam-Jacobi, M. A. Pallen, T. Gaillard Thomas, and from Lowell, Dr. Nathan Allen, send opinions which are quite harmonious in their condemnation of the present method of education.

In Europe the statement of Dr. Freichler was quoted to the effect that in Paris, Nuremburg, and Darmstadt, one-third of the pupils in the schools suffer from habitual headache, attributed mainly to bad hygienic surroundings in school, combined with overwork and worry. The practical results of a medical inspection of the public schools in Brussels are shown to have been an improvement in the general health, freedom from epidemics, and an apparent diminution in the number of juvenile paupers and delinquents.

In the report thus made to the Cleveland Board, it is evident that two sides of the question are

brought up—the sanitary and the educational, the school-house and the pupil. The improvement in the school-houses, the attention to the details of lighting, airing, seating, of school hours, etc., is something of which the need is apparent. Reform here can doubtless be secured without any prolonged and tremendous agitation. The allied subjects of just what to teach and how to teach is a more difficult one. Progress here must wait upon the slow change of public opinion.

---

PARANGI—A NEWLY DESCRIBED DISEASE.

A PECULIAR contagious disease, called frambœsia, or the yaws, has long been known to exist in Africa, the West Indies, and the northern parts of the British Islands. It is chronic in character and is distinguished by the development of raspberry-like tumors of granulation tissue on different parts of the body.

A disease of a somewhat similar, but severer type, has for many years prevailed in Ceylon. Even less was known of this affection than of its supposed congener, until a recent careful report upon the subject by Mr. W. R. Kinsey, Principal Civil Medical Officer of Ceylon.

The disease in question is called "Parangi," and is defined by Mr. Kinsey (*British Medical Journal*) as a specific disease, produced by such causes as lead to debilitation of the system; propagated by contagion, generally through an abrasion or sore, but sometimes by simple contact with a sound surface; marked by an ill-defined period of incubation, followed by certain premonitory symptoms referable to the general system, then by the evolution of successive crops of a characteristic eruption, which pass on in weakly subjects into unhealthy and spreading ulcers whose cicatrices are very prone to contraction; running a definite course; attacking all ages, and amenable to appropriate treatment.

The disease seems to develop especially in places where the water-supply, which in Ceylon is kept in tanks, is insufficient or poor. The bad food, dirty habits, and generally unhygienic mode of life of the people, helps on the action of the disease.

Parangi, when once developed, spreads generally by contagion from the discharges of the eruptions and ulcers. The natural secretions do not convey the poison. The disease may be inherited also.

In the clinical history of the disease there are, according to Mr. Kinsey, four stages. The first is that of incubation. It lasts from two weeks to two months. A sore will be found somewhere upon the body at this time, generally over some bony prominence. The second is the stage of invasion, and is characterized by the development of slight fever, *malaise*, dull pains in the joints. As this stage comes on the initial sore heals. This second stage lasts only from two to seven days, and ends with an eruption which ushers in the third stage. The eruption appears in successive crops, the first often showing itself on the face, the next on the body, and the last on the extremities. This eruptive stage of the disease continues for several weeks or months, and it ends either in convalescence or the onset of a train of sequelæ, which may prolong the disease for years.

Parangi may attack any one, though the poorly fed and housed are more susceptible. One attack seems to confer immunity from another.

Although some of the sequelæ of the disease are most painful, yet death does not often directly result from them, nor is parangi itself a fatal disease. Persons who have had parangi and passed safely through it, are not left in impaired health at all, but often live to an old age.

The similarity of the disease, in its clinical history, to syphilis, is striking. Mr. Kinsey, however, considers it as we have stated, allied to, if not identical with frambœsia.

# Reports of Societies.

## NEW YORK PATHOLOGICAL SOCIETY.

*Stated Meeting, October* 26, 1881.

DR. T. E. SATTERTHWAITE, PRESIDENT, IN THE CHAIR.

(Continued from page 613.)

CARIES OF THE TARSUS—AMPUTATION AT THE TIBIO-TARSAL ARTICULATION.

DR. JOHN A. WYETH presented a foot removed from a Confederate soldier on account of a gunshot wound received nineteen years previously, in April, 1862, at the battle of Shiloh. It was received on the first day of that battle while in the act of running toward the enemy. The ball entered on the fibular side of the foot, traversing the calcaneo-cuboid articulation and the articulation between the astragalus and the scaphoid; making its exit on the tibial side of the foot. After suppurating and discharging some pieces of bone, the wound closed up, seemingly healed, about seven months after the injury. For six years the foot was perfectly well and useful, when, without any known provocation, it became inflamed, painful, and suppurating. This condition continued with varied intervals of improvement during the years included between 1869 and September, 1880, when he came under Dr. Wyeth's observation. The gentleman had, since the war, resided in Texas, leading quite an active life as a cotton-buyer. When Dr. Wyeth examined his foot in 1880 there was considerable swelling, a suppurating wound on either side at the points of entrance and exit, and a tortuous sinus connecting these openings, through which a probe was passed with difficulty. The patient suffered intensely at times with pains, which extended to the toes and often up the legs; was much emaciated, and had grown accustomed to the use of opium to relieve his suffering. After consultation with Drs. F. H. Hamilton and E. A. Banks, it was decided to make an effort to save the foot. Both wounds were freely opened, some pieces of carious bone removed, the anterior tibial nerve divided, and

a hole was drilled through the foot along the track of the bullet, and a rubber drainage-tube, one-fourth of an inch in diameter, passed through and left in position. The patient recovered slowly, but was not relieved by the operation. He returned to Texas, but in May, 1881 (eight months later), again presented himself for treatment. On May 28th, Dr. Wyeth amputated the foot at the tibio-tarsal articulation, performing the operation recommended in the Prize Essay of the Bellevue Alumni Association for 1876; especial care being taken to carry the lower incision well forward, in order not to wound the plantar arteries near the bifurcation of the posterior tibial. The operation was done under the spray. A drainage-tube was left in the flap, passing out at the most dependent portion. The wound healed by first intention, except where the tube made its exit. The patient recovered promptly, had improved in health very much, suffered no pain whatever, and was wearing an artificial foot with as much comfort as could be expected so soon after the amputation.

Dr. Heineman presented a specimen of

CARIES OF THE PETROUS PORTION OF THE TEMPORAL BONE FOLLOWING CHRONIC EAR DISEASE.

The patient was admitted into the Roosevelt Hospital, July 13, 1881, with an indefinite history of illness lasting one week. He was delirious at the time of admission, his temperature rose to 107° F., and he died July 15th. Subsequently it was ascertained that the patient had a discharge from the right ear, which had ceased before entering the hospital. At the autopsy caries of the anterior and posterior surfaces of the petrous portion of the temporal bone was found. The outer surface of the dura mater covering the bone was coated by a considerable layer of recent fibrine and pus. There was a recent clot in the right petrosal sinus. The vessels of the pia mater were congested, with here and there scanty traces of pus over the convex surface of the right middle lobe of the cerebrum. There was aortic and mitral insufficiency, with dilatation of left ventricle and hypostatic congestion of the lungs. The liver was congested. The spleen weighed twenty ounces, congested, and somewhat soft. The kidneys were the seat of parenchymatous degeneration. The stomach presented the lesions of chronic catarrhal gastritis. The Peyer's patches of the small intestine presented well-marked shaven-beard appearance.

THE SHAVEN-BEARD APPEARANCE OF PEYER'S PATCHES.

Dr. Heineman also presented a portion of the ileum, which exhibited a swollen condition of Peyer's patches, the so-called "shaven-beard appearance," and in that connection he directed attention to the fact that the condition was frequently found associated with other diseases than typhoid fever, of which it had been considered by some as characteristic, whereas the truth was that the Peyer's patches might not be involved in some of the genuine cases. He had been informed by Dr. Janeway that during the last epidemic of typhoid fever which occurred in New York, Peyer's patches were not involved in the cases in which he had opportunity to make post-mortem examination. Dr. Heineman had seen the shaven-beard appearance (specimens presented to the society) associated with three distinct diseases, meningitis, with high temperature, cholera morbus, and general pyæmia, and he recalled a case in which Dr. Delafield made an autopsy and found the shaven-beard appearance well marked after an extensive burn.

COMPOUND COMMINUTED FRACTURE OF THE SKULL.

Dr. William H. Porter presented a brain removed from the body of a patient, Thomas C——, forty years of age, who was admitted to the service of Dr. George F. Shrady, at the Presbyterian Hospital, October 8, 1881, with the following history, furnished by Dr. Simpson, house surgeon.

About an hour before admission, the patient fell from a ladder a distance of about thirty feet. On admission he was comatose, somewhat irritable; there was general flexion of limbs, with rigidity somewhat more marked on right than on the left side. The surface of the body was cold, and the pulse very feeble. There was hemorrhage from the nose and the right ear. There was extensive ecchymosis and distention of both eyelids, a small wound and hæmatoma over the left temporal region, leading down to a comminuted fracture. There was a large hæmatoma over the right parietal region. The patient continued comatose, and died five hours and a half after admission.

Necropsy by Dr. Simpson, house surgeon, twenty hours after death. Rigor mortis fairly marked. Body well nourished. Ecchymosis around the eyeballs. A large hæmatoma under the scalp on the left side.

*Thoracic cavity.*—The pericardial sac contained three drachms of serous fluid, a small milk patch was on the anterior surface of the right ventricle. A very small amount of fluid blood in the left cavities; a larger quantity and a small amount of coagulum in the right cavities of the heart. Weight of organ, thirteen ounces. Valves free and sufficient. The *left* lung adherent to the diaphragm, but otherwise free in the pleural cavity. There was a small quantity of bloody serum in the left pleural cavity. The second, third, and fourth ribs were fractured midway between their angles and the costal extremities. Weight of the left lung, twenty ounces. The *right* lung was free in its pleural cavity. Weight, twenty-eight ounces. Both organs were deeply congested and œdematous.

*Abdominal cavity.*—Numerous ecchymotic spots were visible on the small intestine, located just underneath the peritoneal coat. The bladder was distended with urine. The spleen was soft and flabby; weight, three ounces. Kidneys: weight of the left, six, of the right, four ounces. Gross appearance, nearly normal. The liver was small and slightly fatty. Weight sixty five ounces.

*Cranial cavity.*—When the scalp was turned back a large blood-clot was found between it and the skull, the scalp being cut through at one point, as a result of the original injury. There was a compound multiple fracture of skull involving the right and left temporal, the left parietal, the sphenoidal and the frontal bones. The centre of the destruction was at the junction of the left parietal, temporal, frontal, and sphenoid, the bones being broken into nineteen small fragments. From the point of union between the anterior inferior angle of the left parietal and frontal bones the fracture ran inward and forward in a serrated manner across the orbital plate of the frontal, to the cresta frontalis one-fourth of an inch anterior to the foramen cœcum; from this point the fracture was traced backward and outward across the right orbital plate, chipping off the tip of the lesser wing of the sphenoid, thus entering the sphenoidal fissure; from the outer margin of the fissure

it was traced inward and backward until it came within one-eighth of an inch of the foramen ovale, when it turned and ran directly outward for five-eighths of an inch. Again turning nearly at a right angle it ran directly backward, terminating in the petrous portion of the temporal bone at the "hiatus fallopii." From the last angle mentioned an irregular fissure ran outward and upward across the squamous portion of the right temporal bone. On the left side a second fracture across the orbital plate was seen, running from the fracture already described. Starting one-fourth of an inch to the left of the crista frontalis, it ran backward and through the base of the lesser wing into the internal side of the left sphenoidal, back across the great wing of the sphenoid just external to the foramen rotundun and ovale, and terminated in the petrous portion of the right temporal at the "hiatus fallopii." As a result of this double fracture of the orbital plate of the frontal and lesser wing of the sphenoid on the left side, there was an isolated triangular piece of bone, the apex forward and depressed into the orbit, the base directed posteriorly and elevated into the cranial vault, thus lacerating the inferior surface of the anterior lobe on this side.

The interest relative to the brain, was the deep congestion of the meninges, and a large clot of blood resting upon the convexity of the left hemisphere. The major portion of this clot, as diagnosticated before death, rested on both sides of the fissure of Rolando, evidently producing a decided compression of the posterior half of the first and second convolutions, the anterior and posterior central, the supra-sylvian or supra-marginal, and the anterior half of the upper parietal convolutions.

### CANCER OF THE STOMACH.

Dr. Porter also presented a carcinomatous stomach with the following history, furnished by Dr. E. B Ramsdell: The patient was a man sixty-five years old, who in August, 1880, first began to suffer from what he supposed was neuralgia of the stomach. Previous to that date he had had a variety of diagnoses from different physicians, such as Bright's disease, diabetes, cancer, etc.

In October, 1880, he had for the first time an elevation of temperature and the diagnosis of malarial fever was made, and the patient changed his residence. From that time until March, 1881, he had no special symptoms except a slight pain in the epigastrium, sometimes extending through to the back and under the scapula, and burning in character. He gradually lost flesh and strength between October and March, and at several different times the physicians detected, as was supposed, enlarged lymphatic glands in both iliac regions, but at the autopsy no enlargement was found. About the middle of March the patient came under the care of Dr. Ramsdell who restricted him to a fluid diet which was continued until the latter part of March when he disobeyed orders, took solid food and vomited for the first time. It did not continue, however, nor was nausea and vomiting a marked symptom at any time during the entire course of the disease. From March until the time of his death the fluid diet was continued.

From the cachectic appearance of the patient, the steady loss of flesh and strength, and thepain erferred to in the epigastrium, the right hypochondriac region, and through to the back, though only moderate in severity, it was suspected that cancer existed. No positive diagnosis was made, however, until about the middle of July, when Dr. Ramsdell first detected a tumor, and then believed that he had to deal with cancer of the stomach. Dr. George F. Shrady then saw the patient in consultation, and confirmed Dr. Ramsdell's diagnosis.

The specimen was interesting from the fact that the cancer evidently began in the lesser curvature of the stomach, a fact which aided in explaining the obscurity of the early symptoms. Although the disease ultimately surrounded the stomach it did not absolutely encroach upon the pyloric orifice, and perhaps that might explain why the patient had no vomiting after being placed upon an exclusively fluid diet.

Dr. Briddon thought that vomiting was not a common symptom in cancer of the stomach where the disease did not involve the pyloric extremity.

The President remarked that several specimens had been presented to the society which substantiated the statement that when cancer did not involve the pylorus vomiting was not a prominent symptom.

Dr. Shrady said that the absence of vomiting was considered in Dr. Ramsdell's case, and from it the diagnosis was made that the cancer was not situated at the pylorus.

### UNILATERAL NEPHRO-LITHIASIS—COMPLETE OBLITERATION OF ONE KIDNEY AND CHRONIC DIFFUSE INFLAMMATION OF THE OTHER.

Dr. E. C. Wendt presented specimens of the above, accompanied by the following history, which had been furnished by Dr. David Haig, House Physician of the St. Francis' Hospital: The patient, a native of Ireland, was fifty years of age, and a widow. She was admitted to the hospital on October 8th, in the service of Dr. Lellmann. She had generally enjoyed good health, and remembered no serious previous illness. She had been accustomed to indulge, as she said, moderately in alcoholic drinks. Her sickness, she stated, began about two years ago with pain referred to the epigastric region. The nature of the pain was described as sharp and lancinating, with radiation backward into the loins. Soon the pain became constant, and gradually it increased in severity. Acute paroxysms or colics she did not mention as having occurred.

Some six months ago the patient noticed a rather rapid loss of flesh and strength, while the skin assumed a dirty yellowish complexion. From this time until her death there was progressive emaciation. About six weeks before her admission to the hospital she began to vomit, and the rejected substances had a greenish black appearance. When she entered the hospital there was a pronounced cachexia, great emaciation, and utter prostration. There was also persistent vomiting of a greenish fluid, having a very offensive odor. The liver was found enlarged, and the hepatic region tender to the touch. Slight œdema of both lungs was also present. The pulse was weak, 124 per minute. The temperature about 98½° F., and the respiration 32.

The urine contained fifty per cent. (by bulk) of albumen—a microscopical examination was unfortunately not made. During the five days of her stay in the hospital there was but little change in the patient's condition. The vomiting was temporarily controlled, and the pain somewhat allayed. But she soon refused all nourishment and passed into a state of more or less profound stupor, from which she could only with some difficulty be roused. Death took place at night on October 23d.

An autopsy was made by Dr. Wendt on the next day, and the following notes were taken:

There was some serous fluid in both pleural cavities. The lung on the left side, particularly near the diaphragm, was bound down by old adhesions. General pulmonary œdema was also present on both sides.

The *heart* showed great hypertrophy of the left ventricle, and there were the usual signs of a recent fibrino-serous pericarditis. All the valves were healthy. The muscular substance was abnormally soft, which was apparently due to slight fatty changes.

In the abdominal cavity a small quantity of slightly turbid fluid was found. No evidence of peritonitis, either general or local.

The *liver* was enlarged, flabby, and fatty, but very rich in blood.

In the *stomach* a very marked hypertrophy of the mucous membrane was discovered. There were conspicuous rugæ, superficial ecchymoses, and the entire surface was coated with a thick layer of viscid slime.

The *spleen* was fixed to the diaphragm above, and to an indistinctly circumscribed mass of hard tissue below. Its substance was friable, and the whole organ, though reduced in size, appeared congested.

The mass of tissue just mentioned corresponded in position to the left kidney. It was removed with great difficulty, and a portion of the spleen was still firmly attached to it.

On examination it was discovered to represent the remnant of the completely obliterated *left kidney*. Intercommunicating fibrous channels and pockets, lined with a velvety mucous membrane, alone remained to tell the tale of a completely wasted kidney. Not a trace of renal parenchyma was visible. At the lower end of this multilocular sac, which corresponded to the dilated renal pelvis, a branching, slightly adherent, blackish calculus was found embedded. Infiltrated adipose tissue, outside of a thick, hard capsule, surrounded the entire mass.

The *right kidney* was but slightly enlarged. Its capsule was adherent here and there. The external surface was bossed, and had a variegated appearance owing to the difference in color between the protuberances and depressions. On section, no lines of demarcation between a cortex and medulla were visible. Here and there a pyramid was faintly marked. The surface had a dusky reddish hue, relieved by variously sized patches of lighter color. Microscopical examination revealed the characteristic changes of a chronic diffuse nephritis.

Dr. Wendt thought the case an exceptional one, and interesting both in its clinical and pathological aspects. First, in regard to the clinical history, as far as could be ascertained, the most prominent symptoms had been gastric rather than renal. At least the stomach symptoms had predominated. Renal colics apparently had never occurred. Acute uræmic symptoms came on only toward the close of life. Yet one kidney was completely wasted, and the other in a very poor condition for the healthy performance of its function. And doubtless both conditions had existed for a long period.

Moreover, there was no vicarious hypertrophy of the right kidney to compensate for the gradual loss of the left one. Doubtless the interstitial renal changes had prevented such an enlargement. The calculus must have blocked up the ureter, and in addition caused a suppurative pyelitis, which then led to dilation of the renal pelvis and calices, and finally so encroached upon the secreting tissue of the kidney as to result in a complete atrophy of the parenchyma. The true gastritis, as manifested by a much thickened mucous membrane of the stomach, was probably caused in the first instance by the abuse of alcoholic beverages. But the persistent vomiting of offensive fluid toward the close of life was doubtless caused through an overloading of the system with urates, and should be interpreted as a subacute uræmia.

Dr. Ripley thought that persistent vomiting was a very prominent symptom of kidney disease, and that it was likely to be associated with considerable pain. Persistent vomiting should always lead to an examination of the urine.

Dr. Briddon thought that persistent vomiting was by far the most constant symptom in uræmia, but he did not think that pain was commonly associated with it. He doubted the propriety of arresting the vomiting in such cases.

Dr. Ripley said that the best method for arresting the vomiting was to eliminate the urea, and the next best agent was morphia.

Dr. Briddon thought that with kidneys such as Dr. Wendt had presented, no evidence of kidney disease would be found by examining the urine, on account of the presence of pus which doubtless accounted largely for the albumen present in this case.

Dr. Heineman remarked that he understood fifty per cent. of albumen had been found in the urine. He had heard no reference in the history of the case to any microscopic record. He was little inclined to accept the view suggested that this albumen was entirely owing to pus. The quantity of liq. puris to furnish fifty per cent. of albumen must be very great, and the pus would then have been noted even from naked-eye observation. The quantity of albumen could be well accounted for by supposing that the patient had an acute exacerbation of his chronic nephritis.

Dr. Ripley thought that if albumen was not found in the urine, we were not likely to find any other evidence of kidney disease.

The President remarked that Dr. Ripley's statement would not hold good in most cases. With the variety of kidney presented by Dr. Wendt—the small contracted kidney—albumen might be frequently absent from the urine. Therefore the case was the more remarkable.

Dr. Wendt remarked that there was evidently an acute attack engrafted upon a chronic disease of the kidney, and it was that which killed the patient.

### LEUCOCYTHEMIA: INVOLVEMENT OF THE SPLEEN, LIVER, AND LYMPHATIC GLANDS.—DEATH FROM RETRO-PERITONEAL HEMORRHAGE.

The President presented the spleen and liver from the above case, and gave the following history:

K. F——, aged seventeen, German, single, was admitted into St. Luke's Hospital on October 18, 1881. Nothing was elicited of her family history tending to show that she had inherited any constitutional taint. Her father and mother and nine brothers and sisters are living, and said to be in good health. At seven years of age she had measles, but it was not thought to have had any sequelæ that affected her subsequent health. In the four months preceding admission she had not menstruated, and in this respect she had always been irregular. When the periods stopped, she observed a swelling on the left side of her abdominal cavity, and it occasioned her pain for two days.

She then began to lose flesh, but subsequently regained it. Soon she began to have dyspnœa, and, five weeks previously, frontal headache, coming on in the afternoon and lasting two hours. A month previously she noticed discoloration (ecchymoses) upon different parts of the limbs. Bowels were regular and appetite good. Her general appearance did not indicate anæmia. On palpation the tumor was found by the attending physician (Dr. A. B. Ball) to be in the enlarged spleen, and an examination of the blood by the microscope having shown that the white corpuscles were in very great excess of the red, the diagnosis of leucocythemia was given. On October 22 (fourth day after admission) a large tumor was discovered in the right hypochondriac region. This increased somewhat rapidly in size, and was accompanied by pain and vomiting. Fourteen hours subsequently she died, with the symptoms of exhaustion from loss of blood.

The cause of death was attributed by the attending physician to a sudden retro-peritoneal hemorrhage, which at post-mortem examination was verified.

*Autopsy* (twenty hours after death).—Body in a fairly good state of nutrition; no emaciation. The two tumors, one on the left and the other on the right of the spinal column, could be distinctly appreciated by palpation, but their limits could not be distinctly defined by percussion. The left tumor could be lifted up along its right margin, and its convoluted edge might even be felt through the abdominal pareses. The right tumor was immovable, more deeply seated, and its limits were ill-defined. It was also softer to the feel. Vagina admitted the forefinger with some difficulty. Uterus in normal position; freely movable.

On exposing the *peritoneal cavity*, it was found to contain twelve ounces of blood-serum.

The *spleen* was found to extend from the diaphragm obliquely downward, so that its lower extremity rested against the symphysis pubis. It had risen from its normal position and become quite superficial, partly overlying the intestines for all of its length. Weight, four and three-fourth pounds. It contained no tumors, but had a grayish brick-red color, and was firm and solid, much like a lung in a state of red hepatization. The pericardial sac contained one and one-half ounce of clear serum. The *right lung* was free and normal. The *left lung* was attached posteriorly and inferiorly by four pleuritic adhesions. The heart-substance was also soft, and the blood in its cavities a maroon-red color, and was imperfectly clotted. Weight of heart, nine ounces.

*Liver*—In this organ was a tumor (lymphatic) as large as a pear, just beneath the posterior and under surface of the right lobe. The substance was unusually soft, almost diffluent. Weight, six and one-half pounds.

The *left kidney* was pale; its capsules neither thickened nor adherent. The cortical markings were not irregular. In the pelvis, which was not inflamed, there appeared to be pus, which in one instance, could be traced up to a cheesy-looking papilla. Weight, five ounces.

The right tumor was found, on turning back the intestines, to be due to a retro-peritoneal extravasation of blood. It extended from the sixth rib, in the mammary line, to the level of the anterior superior spines. Pressing the peritoneum forward, it formed a heart-shaped tumor, having its apex directed upward and its base downward, while the greatest convexity corresponded to a line drawn horizontally across the free borders of the ribs. Attached to the peritoneum, over the lower and anterior portions of the tumor, lay the vermiform appendix, having a direction longitudinal to that of the body.

The ileo-cæcal valve was raised to the level of the anterior superior spines. The blood-clot composing the tumor was of a maroon color, and pasty. It weighed sixty-seven ounces. In its centre was the right kidney, the condition of which was not essentially different from the left. Its pelvis also contained yellowish matter, looking like pus.

The *retro-peritoneal glands* were found enlarged and infiltrated; color, a dull gray.

Blood from the hepatic vein, the heart, and the supposed pus from the kidneys was examined microscopically. The white corpuscles were found to occupy fully three-fourths of the field of the microscope. The red were much altered in appearance. With them were also found great numbers of the smaller corpuscles (microcytes) that had been observed in similar cases. There were also present the peculiar octagonal crystals described by Charcot, and found in leucæmic blood.

The cause of the hemorrhage in this instance was attributed to the fatty condition of the vessels—a peculiarity of the disease. The hemorrhage apparently proceeded from a minute vein, possibly the phrenic or supra-renal, upon which, doubtless, great strain was brought, due partly to the obstructing influence of the enlarged liver, and partly to the pressure of the diseased lymphatic glands. The supposed pus in the kidney proved to be epithelium thrown off from the pelvis of the kidney.

### PISTOL-SHOT WOUND OF THE THIGH—PERFORATION OF THE FEMORAL ARTERY—EXTRACTION OF THE BALL AND LIGATION OF THE VESSEL.

The President presented a pistol-ball and drainage-tube with hair-lip pins, connected with which was the following history:

W. T. L——, a young man living in his neighborhood, was accidentally shot through the right thigh on December 10, 1880, the bullet entering the thigh on its anterior aspect about the junction of the upper and middle thirds, and just over the sartorius muscle. The patient presented himself a few hours after receipt of the injury, and the swollen condition of the limb, the expansive pulsations in it, and the diminished pulse in the tibials, immediately excited suspicion that the femoral had been injured. No probing was resorted to, as the bullet was plainly to be felt beneath the skin in the popliteal region below the joint. It was removed after incision of the skin and without any anæsthetic. After closure of the two wounds with adhesive plaster, the entire limb was evenly compressed by a rubber bandage. The patient returned to his home on foot, going at once to bed. The pain increased, however, and he soon complained of a "bursting" sensation in the thigh. As the pulsation was now more strongly marked, a compress, with spica-bandage, was applied over the femoral in the groin. This procedure afforded only partial relief, and it was subsequently determined to accomplish the same object by flexing the thigh upon the pelvis, a compress (in this case a roller-bandage) being inserted over the vessel between the thigh and pelvis. Under this treatment it soon became apparent that there was a circumscribed tumor in the course of the femoral, and corresponding to the junction of the lower and middle third of the thigh. A consultation was accordingly held with Dr. J. L. Little, who sanctioned an operation, the

object of which was to expose the blood-sac and tie the wounded vessel above and below the wound. This operation was done on December 19th, with the assistance of Drs. Little and G. F. Shrady, and under full antiseptic precautions (Lister's method). An incision, eight inches in length, having for its upper limit the external wound, was carried down over the course of the femoral vessels. A mass of firm blood-clot, the size of one's two fists, was thus brought into view and removed by the hand, while smaller masses of clotted blood were taken from the intra-muscular planes. The sheath of the femoral was then exposed above Hunter's canal for about two inches, but the injured point could not be found. It was then decided to open the canal, and the dissection was accordingly carried still further downward. The wound in the vessel was then found just two and one-half inches above the upper limit of the popliteal space. It was detected by the fact that the walls of the vessel were denuded just around the opening, giving this spot a peculiar white appearance. The bullet (calibre 22 short) had cut a hole out of the side of the vessel passing close to the vein and nerve. The limb had been rendered bloodless by Esmarch's bandage. All the arteries were tied with carbolized gut, and the ends were cut short and left in the wound. Owing to the great depth of the incision, and the laceration of soft parts occasioned during the prolonged search after the wound in the vessel, it was thought best not to unite the edges of the wound by the ordinary silk sutures, but to insert hare-lip pins instead. A drainage-tube also was laid deeply in the wound with its two extremities exposed. The delayed union in this case was evidently due to the fact that the gut was only in part absorbed, for at intervals small portions would work their way to the surface and be found in the discharges at the time of dressing the limb. Temperature on the same evening, 100° F. in the axilla. It reached its maximum on the third day (December 22), when it was 101° F.; two of the pins were then removed. On the fifth day two other pins were removed; and on the ninth day, the last remaining pins—axillary temperature at this time 99° F. No unfavorable symptoms followed, and the patient left his bed on January 30, 1881. On May 1st the wound was found to be completely healed, but the patient limped. When examined in October, 1881, this symptom had disappeared. Pulsation in the limb never returned, but there still continued to be some pain in the knee and a numbness in the leg. At the present time the patient's health is entirely restored.

As minor points of some pathological interest in the case, attention was directed to two facts which were corroborative of observations that have been made in similar instances. *First.*—That the carbolized gut is not always absorbed, and, indeed may actually retard the union of a wound. *Second.*—That it is not always easy, even under exceptionally favorable circumstances, to find the site of injury in a vessel that has been opened into. In this particular instance, when the locality of the injury was definitely known within a tolerably limited area, full one hour was consumed before the wound could be found, and then attention was only drawn to it by holding in view the consideration already alluded to. Obviously then, in penetrating gunshot wounds of large calibres, where hemorrhage has occurred, the difficulty of finding the precise site of injury to a vessel would be still greater.

The society then went into executive session.

## NEW YORK SURGICAL SOCIETY.

*Stated Meeting, October* 11, 1881.

DR. H. B. SANDS, PRESIDENT, IN THE CHAIR.

(Continued from page 607.)

### GUN-SHOT FRACTURE OF THE FEMUR—TETANUS.

DR. L. M. YALE presented a pathological specimen accompanied with the following history:

A man, aged twenty-seven, while fighting with a detective, was shot in the left thigh as he stepped to the street from the sidewalk, and as the ball struck him his limb gave way. The ball entered the outer surface of the left thigh, three inches above the articular surface of the femur, and the point of exit was upon the opposite side, four inches above the articular surface. Under anæsthesia the wound on the outer surface of the thigh was enlarged, the finger introduced, and the hole in the femur distinctly felt. The femur was fractured about one inch above the hole made by the bullet. The upper fragment was sharp-pointed, and displaced forward, overriding the lower fragment and piercing the muscles. The lower fragment was displaced backward. Several loose fragments of bone were found beneath the muscles, two of which were removed. The joint-capsule was not injured. The wound was washed with carbolic acid, 1 to 20, a drainage-tube inserted, and the full Lister dressing applied. A long side-splint was used, and Buck's extension with fourteen pounds. The patient was admitted to Bellevue Hospital September 5, 1881, and on September 6th the Lister dressing was reapplied and the limb placed on a Volkmann's apparatus. The dressing was reapplied on September 7th, and on September 8th the large drainage-tube was removed, and smaller tubes, an inch and a half long, were inserted into each end of the wound. The Lister dressing was reapplied.

September 20th.—The patient has progressed favorably. A simple dressing of borated cotton and balsam of Peru was substituted for the Lister, and the limb was put up in a plaster of Paris splint. Fenestræ were cut, so as to expose the wound on each side, which was washed out daily with carbolic acid, 1 to 40, and dressed with borated cotton and balsam of Peru. Patient feels well and complains of no pain.

October 1st.—He complained that his throat was sore, which was attributed to an open window near his bed. There was considerable stiffness of the jaw. The wound looked healthy and discharged about two ounces of laudable pus.

October 2d.—Patient still complains of sore throat, stiffness of the jaw, and some difficulty of swallowing. No change in the condition of the wound.

October 3d.—The patient complains that he cannot open his mouth, and says that his jaw closes occasionally with a sharp snap, his teeth cutting his tongue, and that he has had much difficulty in swallowing.

At 9 P.M. he complained of twitchings in the injured leg, starting from the malleoli. Splint cut down to relieve pressure. No ulcers found. The twitchings continued, the difficulty in swallowing increased, the stiffness of the jaw remained, and on October 6th, at 1 A.M., he had a general tonic convulsion, which lasted about fifty minutes, with pleurothotonos, rigid neck, rigid and flexed arms, slight risus sardonicus, and pulse 140. Respiratory movements very limited during convulsion. At 3 A.M. he

had another but more pronounced convulsion, and at 5 A.M. the third convulsion appeared, during which he died of apnœa. At the autopsy there were no evidences of septicæmia or pyæmia. There was in the canal of the bone some evidence of exfoliation, and the portion removed was in a condition of rarefying osteitis.

DR. STIMSON thought the specimen was interesting as showing the condition of a fracture one month after the injury was received, and which had done well during that time.

DR. A. C. POST queried whether tetanus had occurred unusually frequent this season, and referred to the fact that he had met with two cases of traumatic tetanus in two successive days; one from a rusty nail in the foot, and the other from an inflamed condition of the navel. Both cases terminated fatally, and both occurred in the month of August.

FOREIGN BODY REMOVED FROM THE BLADDER.

DR. LANGE presented a specimen which he had removed from the bladder by median cystotomy. A man, thirty years of age, became totally drunk, and while in that condition his friends amused themselves by introducing into his urethra, one after another, small pieces of pitch. During the first six or seven weeks afterward the man passed some of them in his urine without knowing what they were. Several attempts had been made to remove others by lithotrity and forceps. He first tried to make aspiration through Bigelow's large tube, but did not succeed, and then performed median cystotomy, and removed the specimen presented, which was nearly two inches long and half an inch in diameter.

DR. KEYES presented a specimen of

URINARY CALCULUS,

with the following history:

"R. M——, a thin, wasted old man, sixty-eight years of age, with trembling hands and tottering gait, on October 3, 1881 (one week ago yesterday), had in his bladder the stone of which I present the fragments to-night for your inspection.

"The stone is composed of uric acid and urates. It weighs, dry, 1,065 grains. It was extracted by Bigelow's method in one hour and a quarter—seventy-five minutes—being an average of about fifteen grains of stone to the minute.

"The instruments used were my own lithotrites, Bigelow's tube, 27 French (16 English), and Thompson's washer.

"No complication occurred. I was assisted by Drs. Stimson, O'Dwyer, and Blackwell.

"No chill followed the operation: no urinary fever. My first call at the patient's house was on the day of the operation, my last call on Saturday, the *fifth* day, when the patient was declared well, allowed to get up and go out, and professional visits were discontinued.

"The patient had had symptoms of stone for ten years, but the calculus was only detected last summer, by Dr. Van Buren. He was not operated on earlier than last week, because he was sick and feeble, being confined to his bed for a month with what he called malarial fever, but what I, from his account of it, believe was urinary fever—doubtless due to mild pyelitis.

"I expected the patient to have a severe reaction, but he had none. This I ascribe, in part, to the use of a moderate tube, No. 27, the urethra not being cut or damaged in any way.

"I cannot resist the conviction that any other variety of operation would have put the life of this man in serious danger, and I present these brief notes to the society in illustration of the most brilliant triumph of the American operation for stone with which it has been my good fortune to come into personal contact.

"The size of the stone and rate of rapidity in extraction are not the features of this case. The brilliancy consists in the rapid recovery and absence of reaction."

THE PRESIDENT presented two specimens of

URINARY CALCULUS,

one obtained from a patient who did well, and the other from one whose case terminated fatally. The history of the latter case was related first. He was asked by Dr. Pierce, in the latter part of May, to see a gentleman in Harlem, who was afflicted with a stone in the bladder. The patient was seventy-three years of age, and the symptoms of stone had been first noticed about three years ago. The diagnosis was very easy, and it was evident that there was more than one stone in the bladder. The urine was highly purulent; it contained some blood, and was quite fetid; moreover, there was reason to believe that inflammation had extended along the higher portions of the urinary tract. It was a question whether to operate or to leave the man to his fate; but as the patient was suffering, and was desirous of submitting to an operation, Dr. Sands attempted to remove the stone by rapid lithotrity. The attempt was unsuccessful. The patient took ether badly, and became cyanosed; the operation was, therefore, prolonged and incomplete, resulting, after a period of something more than an hour and a half, in the removal of 250 grains of uric acid calculus. The operation was also delayed because it was impossible to introduce an evacuating-tube of larger size than No. 26. The patient did well for thirty-six hours, when he became uræmic, and, although the urine was made to flow, and, by the action of jaborandi, profuse sweating was induced, coma supervened, and he died on the morning of the fourth day. At the autopsy there was found extensive disease of both kidneys, which were in a state of granular degeneration, pyelitis was severe and acute upon both sides. The left ureter was dilated to the size of half an inch. The bladder was extensively diseased, and was, apparently, the seat of old as well as of more recent inflammatory disease, the latter occasioned, perhaps, by the operation. On its mucous surface were a number of patches of lymph, the largest of which was about an inch in diameter, situated at the superior fundus. The mucous membrane was injected and was much thickened in consequence of chronic inflammation. In the bladder was found also a large quantity of crushed stone, and a calculus, probably of the same character as the one removed, which measured an inch and a half in its longest diameter. The weight of calculus material remaining in the bladder was 545 grains, making, together with that removed at the operation, about 800 grains. The case was interesting as showing the danger of an operation in old persons, and, although it was possible that if lithotomy had been performed the patient might have recovered; yet it was probable that a fatal result would have followed any severe surgical procedure.

The other specimen exhibited was one of phosphatic calculus removed on the 30th of June, from a patient, forty-four years of age, who had suffered

from symptoms of stone for four years. The operation lasted an hour and a half, and 465 grains of calculus were removed. The bladder was completely emptied. This patient, like the other one, became much cyanosed under ether, but he did well immediately after the operation, and on the 1st of July the urine, which was slightly bloody at first, became normal, and the patient passed water with more ease than he had done for years. On the night of the 1st of July he had a chill, and his temperature rose to 102° F. No mischief, however, followed the chill, and the temperature sank on the following morning to the normal standard, and did not rise subsequently. He was discharged well on the 12th of July, thirteen days after the operation.

## NEW YORK ACADEMY OF MEDICINE.

*Stated Meeting, November* 17, 1881.

FORDYCE BARKER, M.D., LL.D., PRESIDENT, IN THE CHAIR.

THE Librarian reported that since the last stated meeting one hundred and eighty-three bound and forty-five unbound volumes had been donated to the library.

DR. PURPLE presented, in behalf of Dr. Isaac E. Taylor, an obstetrical work written by M. Dupuy, and published in 1774; also, in behalf of Dr. Austin Flint, a manuscript letter of Laennec.

DR. ADAMS, Corresponding Secretary, announced the death of M. Bouyeau, of Paris.

### TRANSFUSION OF BLOOD.

DR. DUBOIS, of Grand Rapids, Mich., exhibited a new instrument for transfusing blood from one vein directly to another.

DR. LOUIS ELSBERG then read a paper on

### "THE CELL DOCTRINE AND THE BIOPLASSON DOCTRINE."

Introductory to the paper the author gave a *résumé* of his observations on hyaline cartilage, given in full at the last meeting of the American Laryngological Association, and published in the *Archives of Laryngology*. It was to the effect that hyaline cartilage had been considered one of the simplest of tissues, being made up of a dense basis-substance, in which were imbedded soft corpuscles or granular cells. The chief theories in explanation of the manner in which these corpuscles obtained nutrition had been imbibition and the existence of delicate channels in the basis-substance, through which nutrient fluid could pass and reach the granular bodies.

DR. HEITZMAN, of New York, however, had discovered that the hyaline cartilage was really made up of blocks of living matter united by threads of living matter, that is, that hyaline cartilage is a network of living matter, into which lumps of living matter had been placed. The same line of investigation had been extended to the various tissues, and the conclusion reached that the whole body consisted of lumps and threads of living matter united in this manner.

DR. ELSBERG explained the cell theory as represented by Schwann, Virchow, and others, and showed that the word "cell," to designate the organic form element, had long been a misnomer, and claimed that since Dr. Heitzman's discoveries it was not only erroneous, but misleading. Hitherto the amœba had been supposed to consist of a homogeneous, structureless lump of jelly like living matter called protoplasm, containing granules, supposed to be foreign particles; but really it was a mass of living matter arranged into a network, the points at which the threads intersect each other being thickened and constituting the granules supposed to be foreign bodies, and in the meshes of this network was contained the "non-contractile" matter.

He regarded the word "protoplasm" as etymologically incorrect, and preferred the word "bioplasson."

The essential difference between the cell doctrine and the bioplasson doctrine was that, according to the former, each tissue was made up of a number of unities; according to the latter it was composed of masses of living matter interconnected by threads of the same living substance. [See MEDICAL RECORD, vol. x., p. 364.]

DR. C. HEITZMAN said that he made his discovery in 1873, the more theoretical and scientific part of which had been laid before the academy by Dr. Elsberg. There were, however, practical questions closely connected with the doctrine, which, he thought, would form some part of future medicine, as it would enable us to determine the constitutional viability of each individual. What Dr. Elsberg had described as a reticulum of living matter varied greatly in different individuals, and by the aid of the microscope it could be positively determined how much of living matter there was present in each single element of protoplasm formerly called a cell. The white blood-corpuscle was a constituent part of the body, and in it could be found all the features necessary to indicate the amount of living matter in the entire body; in other words, the actual constitution of the individual. [See MEDICAL RECORD, vol. xi., pp. 321 and 322; vol. xii., p. 94; vol. xvi., p. 68.]

### "PYÆMIC PAROTITIS."

DR. C. A. LEALE read a paper on the above subject, in which he spoke of suppuration of the parenchyma of the parotid gland, in contradistinction to the idiopathic affection commonly called mumps. He believed that the primary step in the pyæmic parotitis was ulceration, or solution of continuity at some distant part of the body. He had observed metastatic abscesses in the parotid gland only where ulceration had existed in some part of the body previously. Hence, cases had occurred in connection with typhoid fever, dysentery, suppurative osteomyelitis, diphtheritic ulcer of the posterior fauces, pelvic cellulitis with ulceration, peritonitis, etc., and were embolic in origin.

Dr. Leale then reported several cases and presented two patients who had had suppurative parotitis, which he believed to be due to the cause mentioned.

The *first* was a case in which the abscess broke through and pus discharged from the external auditory canal; it followed acute general peritonitis, and pelvic cellulitis with formation of abscess. Pus could be seen exuding into the external auditory canal, near the membrana tympani. The pelvic abscess opened spontaneously into the vagina. There was also post-pharyngeal abscess, which was opened. The discharge from the ear continued for more than a year. At one time there was complete blindness, complete deafness on the affected side, and nearly total loss of hearing upon the opposite side. The patient ultimately recovered, with hearing and vision completely restored.

The *second* was a case in which, with suppurative parotitis, there was discharge of pus from the external auditory canal on both sides, and there was also complete deafness for three weeks. Hearing in both ears was completely restored.

The *third* was a case in which suppurative parotitis followed typhoid fever, with hemorrhage from the bowels. The abscess communicated with Steno's duct, discharged behind the ear, and nearly, or quite all the gland sloughed away. In this case, as an interesting item in its clinical history, goitre developed, which ultimately disappeared under the use of iodine. The patient was presented to the academy.

Dr. Leale then referred to a number of cases which had fallen under his own observation, others which had been reported by different writers, and in which profuse suppuration had existed, without the occurrence of parotid abscess. From the observation of his own cases, he had been led to believe that suppuration of the parotid gland was best explained by the theory of sepsis; micrococci poison was conveyed from a distant point to the parotid gland, and there developed an abscess or abscesses. He had not seen such metastatic abscesses occur, even with profuse suppuration, provided the pyogenic membrane remained unbroken; neither had it occurred under his observation with the abundant suppuration of empyema. Nor did hospital gangrene seem to be a cause of these abscesses.

Dr. Leale then referred to cases of osteomyelitis which he had reported in the "Surgical History of the War." He also referred in passing to the difficulty of removing the parotid gland, and mentioned cases in which the operation had been done partially or completely by Drs. A. C. Post and William T. White.

The President referred to cases of suppurative parotitis which he had seen in puerperal women. In 1874 he saw a young married woman who had a miscarriage; subsequently pelvic cellulitis;* afterward distinct symptoms of pyæmia, followed by abscess of the parotid gland and death by exhaustion. In Bellevue Hospital he had seen two cases in which the patients died from exhaustion produced by suppurative parotitis of pyæmic origin.

Last winter he saw a patient who had a miscarriage; two weeks subsequently pelvic cellulitis, in which abscess occurred, and two ounces and a half of pus were removed with the aspirator. One week afterward abscess of the parotid developed, which was opened; subsequently the parotid gland upon the other side suppurated. Two weeks after that, ulcerative endocarditis and pericarditis developed, and the patient died two days after the development of the cardiac complications.

Two years ago he saw a case with Dr. Markoe, in which the patient had pyæmia, following the running of a toothpick under a finger-nail. Suppurative parotitis occurred; the pus was deep-seated; the abscess was opened, it discharged freely, and the following morning the patient died of œdema glottidis.

These cases illustrated the fact that the occurrence of suppurative parotitis with pyæmia was not so very rare.

Dr. A. C. Post and Dr. William T. White stated that in their cases it was not known positively that all of the parotid gland was removed.

Dr. Joel Foster referred to a case in which the parotid gland was completely removed by Dr. McClellan, of Philadelphia.

Dr. H. D. Noyes had been interested in listening to the report of Dr. Leale's cases, in which the discharge found its way into the external auditory canal, and also where both vision and hearing were implicated. He thought the discharge into the external auditory canal could find its explanation in the fact that the cartilages of that canal were embryonically developed in parts, and probably a fissure or imperfect fusion remained. Probably these portions of cartilage were less developed in some persons than in others, and at the different points where there was the least resistance the pus might find its way through and make its exit in the direction of the external auditory canal.

Dr. Noyes thought it very remarkable in Dr. Leale's case in which there was deafness in both ears and total blindness, that there should not have been any serious brain-symptoms. The case was probably one of very circumscribed inflammatory action at the base of the skull, which must have affected the sheaths of the optic nerves, and doubtless gave rise to choked optic disc. Ophthalmoscopic examination would have been exceedingly interesting, and probably would have revealed that condition of the respective papillæ. The entire recovery of vision favored the hypothesis that there was nothing more than œdematous effusion. Dr. Noyes then referred to a case in which inflammatory action affecting the semicircular canals followed idiopathic parotitis. The patient recovered, with total and permanent loss of hearing upon one side, and there had been no symptoms of acute inflammation of that ear. There was the characteristic staggering gait, which was never fully recovered from. The precise way in which such results were produced he was unable to say, but the complication was sufficiently common to make the case worthy of special mention.

The Academy then adjourned.

## Correspondence.

### DIET FOR GOUTY PATIENTS.

To the Editor of The Medical Record.

Sir: Permit me to occupy space enough for a short comment on the article of Dr. Alexander Hadden, in the Record of October 22, 1881, in which he advocates an animal diet for the gouty, permitting only such vegetables as contain neither amylaceous nor saccharine principles. He gives cases to show the benefits derived by such patients from a withdrawal of such foods from their diet, and then states the reasonableness of the inference, "that this kind of food may be a factor in the production of this disease in the human system, as well as other well-recognized causes."

After recapitulating the predisposing causes of gout, as laid down by Garrod, he expresses a hope that some physiological experiments might have been made that would either confirm or disprove a hypothesis which he quotes from a former article, as follows: "Whether some fermentation may not take place in the alimentary canal of such animals, birds, and human beings as subsist largely upon a diet composed mainly of amylaceous and saccharine principles, or both, similar to the fermentation which takes place in the manufacture of malt liquor or wines, etc."

It is unquestionably true that amylaceous and saccharine—that is to say, carbonaceous—foods do

play an important part in the production of gout, and the explanation is at hand. One of the functions of the liver, that of oxidizing the albuminoids, furnishes the key to the whole subject as applied to the human race, and to those birds and animals who suffer from gout.

"Lithates cannot be produced from a dietary of hydrocarbons without nitrogen. Hydrocarbons oxidize but slowly when in combination with nitrogen, consequently the more readily oxidizable hydrocarbons burn readily and consume the oxygen of the blood, leaving the albuminoids in an imperfectly oxidized form." The carnivorous birds and animals, who do not suffer from gout, find their analogue in the "gaucho of the South American pampas, who, though a flesh-eater in a hot climate, does not suffer much from lithiasis."

I have quoted these statements from the second edition of Fothergill's "Handbook of Treatment," pp. 405, 406, where a fuller explanation of the subject may be found. Bearing them in mind, I see no difficulty in comprehending the part played by the hydrocarbons in the production of gout, and the rationale of excluding them from the diet of such patients without reference to the hypothesis of Dr. Hadden, and that, too, without at all conflicting with the established custom of excluding the albuminoids; for we may well suppose that the liver, while perfectly competent to oxidize the nitrogenous *tissue-waste*, together with the hydrocarbons, if not overburdened with *nitrogenous food* is equally competent to oxidize the tissue-waste and the albuminoid food if the whole of the oxygen of the blood be left to act upon them, and not be consumed by more readily oxidizable hydrocarbons.

So far as I know, Dr. Hadden is entitled to the credit of being the first to put his gouty patients on a diet from which the hydrocarbons are excluded; but it seems to be so rational, so physiological, that I have no doubt it will prove a valuable addition to our management of the gouty diathesis.

Respectfully,
N. G. THOMAS, M.D.

YALAHA, FLA., November 5, 1881.

## DR. BEARD'S "TRAINED SUBJECT."

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: The letter of Dr. Hammond in the MEDICAL RECORD of October 15th, entitled "A Word for Dr. Beard," being, I think, somewhat inaccurate and misleading in its tendency, may I request, for truth's sake, a little space for some remarks thereon.

It must be clearly understood that the general question of the truth of "hypnotism" is not in any way raised in this matter of Dr. Beard and his "trained subject." That hypnotism denotes a set of well-established facts we all admit; that hypnotism conceives often to cover imposture and quackery is equally certain. The question at issue is whether or not on a given occasion a certain alleged manifestation of hypnotic phenomena was genuine?

To insinuate that Dr. Beard's experiments were discredited by Dr. Crichton Browne and many other observers, on the ground of the assumed falsity of all hypnotic phenomena, is to raise an obviously false issue, enabling the defendants in this controversy to pose as the supporters of a cause instead of an individual, and representing a simple criticism of fact as a covert attack on unwelcome truth.

The universal opinion expressed at the meeting in London, that the experiments of Dr. Beard were wholly unsatisfactory, was an irresistible result of the exhibition itself, quite apart from any preconceived notions on the matter of hypnotism. Were a lecturer on such a well-marked subject as elementary chemistry to fail in every one of his illustrative experiments, or succeed only in one or two which were liable to the suspicion of being "cooked," surely the audience would justly vote the performance unsatisfactory, and demand, at least, some explanation from the lecturer. All the more, then, in a subject so confessedly perplexing as hypnotism, overlaid as it is by designing quackery, and open as it is to unlimited deception, a scientific inquirer is not only to be excused, but imperiously required to make the most rigorous investigation (disregarding every personal factor) of any of its alleged phenomena.

As one of those present at Dr. Beard's London demonstration, and endorsing Dr. Crichton Browne's views, I beg to repeat with emphasis that in the opinion of the whole meeting such an obviously desirable and necessary investigation as I have indicated caused the phenomena before us to melt entirely away. Evidence of this statement has been fully given elsewhere.

I went myself at the invitation of Dr. Beard, in the belief that I was going to see *bonâ fide* examples of hypnotism and obtain as ample information about the patients as I should expect from any physician who brings a case before a medical audience. But Dr. Beard markedly evaded my oft-repeated request for a systematic account of the case before the introduction of those mesmeric phenomena which are so familiar (such as the delivery of florid orations, etc.), and proceeded to behave after the manner of a platform exhibitor rather than of a clinical demonstrator; so that, with no preconceived animus whatsoever, I could scarcely resist the conclusion that this exhibition, at any rate, was unworthy of the audience called together.

With regard to some of the questions asked of Dr. Beard by Dr. Crichton Browne, and answered by Dr. Hammond, I would say:

*First.*—That in hypnotism, where many of the alleged phenomena can be imitated by imposture, and are of a subjective character, it is plainly of the first importance to establish, at least, a *prima facie* evidence of the truthfulness of the subject experimented upon. Any one of moderate histrionic power and seared conscience could easily denounce drunkenness in a verbose harangue, and afterward deny the consciousness of his performance. Yet such an experiment as this was one of those which are supposed to be quite independent of the character of the "subject." When, therefore, Dr. Beard's subject confessed that he was going under an assumed name, and refused, among several other questions, to answer one as to whether or no he had been in trouble with the police, any plain mind would admit that the necessary preliminary inquiry received rather a rude check at the start.

*Second.*—These things being so, any one conversant with even the shallows of the fraudulent rascality of spiritualism would at once see the relevancy of the question as to whether this "trained" subject had been mixed up with this cultus or not. The immediate reason why this man was asked at the meeting if he had sat with mediums, was, that in complaining of having come among a set of "medical doctors," whom he considered to be "wolves," he

said that these experiments were always more successful on himself when the audience was "harmonious." This well-known jargon of the seance-room was followed by the admission on his part *that he had sat with several mediums in New York*, but that he had forgotten their names (though it was only a matter of a few months before). Although Dr. Hammond was doubtless unaware of this admission, his denial of the matter seems unduly positive.

*Third.*—The very irresistible suspicion on the part of all present, although it may not have amounted to absolute demonstration, that all that this subject did on that occasion was "acting," obviously justifies Dr. Crichton Browne's question to Dr. Beard as to whether he, himself, who had observed the patient so much longer, had never entertained a like suspicion.

*Fourth.*—Dr. Hammond's answer to Dr. Browne's question, whether Dr. Beard's statement that he had exhibited his experiments before a certain academy in New York was contradicted by Dr. Adams (the secretary of that academy), is somewhat of a quibble. That Dr. Beard's statement (whatever it was) was at once denied by Dr. Adams every one present could testify. Whether, therefore, the name of the society was correctly quoted by Dr. Browne has no bearing on the question; and Dr. Hammond's irrelevant retort on this head does little credit to his logic.

*Lastly.*—The ethical propriety of Dr. Beard's refraining to express satisfaction that a gross deception had been exposed, depends, of course, on the opinion held as to whether such deception and exposure had taken place. Impartial observers have now the conflicting evidence before them. Let the verdict rest with them.

I am, sir, yours obediently,

H. DONKIN.

LONDON.

## THE POST-MORTEM EXAMINATION OF PRESIDENT GARFIELD.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In the *North American Review* for December, 1881, the "surgical treatment of President Garfield" is discussed by four distinguished men, Wm. A. Hammond, John Ashhurst, Jr., J. Marion Sims, and John T. Hodgen.

The matter is, of course, very ably handled as to most of the points. As to one of them, however, two of the writers make such singular statements, one in an unqualified way, and the other not so clearly, about the effects of injections thrown into the arteries after death, that I think some notice should be taken of them.

Thus, Dr. Hammond, page 586: "That the rupture of the splenic artery was either due to malnutrition of the coats, the result of pyæmia, or was post-mortem, being caused by the injection of a solution of chloride of zinc into the vessels several hours before the autopsy. If the latter was the case, the *blood* found in the peritoneal cavity *was pushed out* by this fluid, which of course filled all of the vessels, and which, it is admitted in the report of the post-mortem examination, was extravasated into the abdominal cavity with the blood."

Then, Dr. Sims, page 598: "The everted edges of the slit in the splenic artery were united by firm adhesions to the adjacent connective tissue. Therefore, the rupture of the artery may have happened during the act of embalmment."

This certainly also conveys the idea that the blood in the abdominal cavity escaped post-mortem.

Have these gentlemen forgotten the very elementary principles and facts of their training as to the blood-vessels? Were they not taught that the very name "artery" is a misnomer, and arose from the fact that the ancients found the arteries empty after death; and that the knowledge of their true uses was not fully made out until the time of Harvey?

Those who have spent years in the sculleries of dissecting-rooms and in the rooms themselves, know practically that nothing is pushed out from *arteries* by injections, for a very plain reason: that there is nothing to push out.

Given a normal condition of the vessels, the last actions of the heart gorge the venous system with blood, and often also the right heart itself.

Preservative watery injections into the vessels, after death, pass on so freely that they rarely, if ever, interfere with the plaster or tallow, or whatever may be thrown in, to aid the student in his studies.

Sometimes these latter injections break the vessels, and masses of the substance are found in the cavities, but never with clots of blood pushed before them.

When a demonstrator in the dissecting-room comes across a large clot of blood in the brain, thorax, or abdomen, he says: "This man died of a hemorrhage!" Very rarely does he find *post-mortem* masses of blood, and when he does find them they have come from veins.

Thus, during the *post-mortem* examination of the President, blood might have poured out from cut or torn veins of the portal system, but this would have been seen and fully noted.

How did the watery solution go in the President's case? It filled the arterial system, and escaped where? Just where blood had escaped *before death* it escaped *after death*. The injection was a good thing, instead of something to be deplored, as is mostly the case in discussions about it, for it helped to prove the existence of an arterial rent or rupture before a knife was put in the body.

The following opinion of a great practical anatomist reinforces these statements:

"According to my experience and observation, the views of the author of the above in regard to the escape of blood from the arteries is correct. In relation with the matter I may tell a story. Many years ago a vigorous male subject had been provided for my lectures on the muscles. It was injected with an antiseptic liquid. After dissection of the muscles on the fore part of the body, this was turned over to prepare those of the back. On removing the skin, an extravasation of blood was noticed in the fascia for several inches over the tendon of the trapezius, at the root of the neck. I remarked to my assistant that the extravasation was due to a hemorrhage preceding death. Later, when the adjacent vertebræ were exposed, a lower cervical was found to be fractured, and partially displaced. We expressed the opinion that the man had died of a broken neck, probably from a fall.—JOSEPH LEIDY, Professor of Anatomy in the University of Pennsylvania."

WILLIAM HUNT,
Senior Surgeon to the Pennsylvania Hospital, formerly Demonstrator of Anatomy in the University of Pennsylvania.

THE GARFIELD MEMORIAL HOSPITAL.—A fund of eighty thousand dollars has already been raised for this object, and much more is promised.

# New Instruments.

## A NEW URETHRAL BOUGIE.

By A. VAN DERVEER, M.D.,

ALBANY, N. Y.

Having had such excellent results from the use of the instrument illustrated by the accompanying cut, I feel it proper to call the attention of the profession to it. In the treatment of urethral stricture by gradual dilatation, and in those cases where it became necessary to maintain the calibre of the urethra after internal urethrotomy, or rapid divulsion, I have realized for a long time that the fixed curve of the steel sound gave unnecessary pain, and that the soft, olive-pointed bougie, by passing some two or more inches farther into the bladder than was required, gave to that organ a shock and an irritation which, in addition to being very disagreeable to the patient, incurred also the dangers of possible cystitis, with its complications.

Acting upon the knowledge of the fact that we seldom, if ever, meet with a stricture in the prostatic portion of the urethra, I had made, some two years ago, by Messrs. Tiemann & Co., light metal urethral dilators, of the average length of the spongy and membranous portion of the urethra—about eight inches—and in sizes ranging from Nos. 10 to 42 of the French scale. These were found very serviceable, being used by patients with safety and success. Later, as an improvement on the above described instrument, I had made, in different sizes, the solid rubber urethral bougie, which gives the least possible pain on passing. These bougies were also made by Tiemann & Co., who are now prepared to furnish them singly or in sets.

Believing them to be the safest of all bougies, and knowing from actual use that they are the most serviceable, I present them with confidence to those of my brethren who have these cases, in the treatment of which such an instrument is indicated.

---

The Transactions of the International Medical Congress will be published and ready for distribution by December. To non-members the price of the work will be 30s. ($7.50). Any volume of the three can be bought separately. The first volume will contain a list of members, accounts of the general meetings, the general addresses, description of the museum specimens, and the transactions of the sections of anatomy, physiology, pathology, materia medica, and pharmacology. Volume two will contain the transactions of the sections of medicine, surgery, state medicine, military medicine and surgery, obstetric medicine and surgery, and diseases of children. Volume three will contain the transactions of the sections of ophthalmology, mental diseases, diseases of the skin, diseases of the throat, of the ear, and of the teeth.

Orders for the work will be received by J. W. Kolckmann, of Langham Place, London.

A Medical Song from "Patience."—

A New York medical man,
A very much-advertised man,
A pills-in-variety, talk-in-Society,
Each-for-himself young man.

A Philadelphia man,
An *Index Medicus* man,
A think-it-all-gammon, this talk of Buchanan,
Great-medical-centre young man.

A Boston medical man,
A hyper-historical man,
An ultra-persimmon toward medical women,
A Harvard-or-nothing young man.

A Chicago medical man,
A wide-awake, ethical man,
A good-as-the-rest-of-you, more-than-abreast-of-you,
Down-on-the-East young man.

Antiquity of the View that Inebriety is a Disease.—The *Lancet*, commenting on the claim made by Dr. Crothers, and others, that inebriety is a disease, says: "It may interest the curious among our readers to know that, even if true, this view is not new. Fourteen hundred years ago a like theory was propounded by St. John Chrysostom, who illustrated his meaning by a reference to the characteristic symptom of craving dyspepsia. 'Do you not see that drunkards are always thirsty? for it is a passion, not the desire of nature, but some perverted disease. Do you not see how those afflicted with bulimy, as it is called, are always hungry?'"

Dr. Alfred H. McClintock, LL.D., of Dublin, Ireland, died on October 21st, in the sixtieth year of his age. Dr. McClintock was Vice President of the Royal College of Physicians, Ireland, Member of the General Medical Council for Ireland. He was chiefly connected, during his life, with obstetrical progress. His most important work was one entitled "Clinical Memoirs on Diseases of Women," published in 1863. Dr. McClintock's last public appearance was as President of the Obstetrical Section of the International Medical Congress.

Dr. Magruder on Genital Irritation.—At the last meeting of the Neurological Society, published in the Medical Record of November 19th, the remarks of Dr. Magruder, of Washington, D. C., were, by a typographical error, credited to Dr. McGuire.

Dr. L. L. Wilcox, long a prominent physician of Hartford, Conn., died on November 25th, at the age of fifty-five years. He was a native of Granby, Conn., a graduate of Yale College, and a member of the Medical Faculty of that university.

"To the Delegates and Permanent Members of the Medical Society of the State of New York: It is desirable that the nature and amount of the scientific material intended for the meetings in February of the Medical Society of the State of New York should be known beforehand, as far as possible. The undersigned, therefore, requests all those, both delegates and permanent members, who propose to read papers, to communicate with him in regard to the subjects thereof, and the time they are likely to consume. If this request be complied with, it is thought that the material can be suitably arranged in groups, fruitful discussions may be prepared, and many who, for public or private reasons, have been prevented from meeting with us on former occasions will be enabled or prevailed upon to attend at least part of the time, and at such a period of the proceedings as will both agree with their special tastes and prove most conducive to the interests of the Society.—A. Jacobi, M.D., President of the Medical Society of the State of New York."

The St. Paul Medical School, which is one of the few requiring four years' study and three courses of lectures, is reported to be well established, and to have $100,000 behind it. We notice, however, in a recent item in the *Mississippi Valley Medical Monthly* that there is no mention now made of *four* years' study, and that students are excused the third course of lectures when they can pass a satisfactory examination in certain elementary medical branches. This may mean almost anything—or nothing.

Medical Society of the County of New York.—At a stated meeting held November 28, 1881, the President, Dr. F. R. Sturgis, appointed the following committees for the ensuing year: *Committee on Hygiene*, Dr. Edward G. Janeway, Chairman, Drs. D. B. St. John Roosa, Stephen Smith, R. H. Derby, and F. M. Weld. *Committee on Ethics*, Dr. James R. Leaming, Chairman, Drs. J. Lewis Smith, Laurence Johnson, Chas. S. Ward, and E. L. Partridge. *Committee on Prize Essays*, Dr. Fordyce Barker, Chairman, Drs. Geo. A. Peters and A. E. M. Purdy. *Auditing Committee*, Dr. Horace P. Farnham, Chairman, Dr. J. Williston Wright.

St. Luke's Hospital, New York.—Dr. J. L. Little has been appointed Attending Surgeon to St. Luke's Hospital, in place of Dr. T. T. Sabine, and Dr. Sabine has been appointed Consulting Surgeon in place of Dr. Little.

American Public Health Association. — The ninth annual session of the American Public Health Association was held November 29th, at Savannah, Ga. There was a large attendance. The meeting was called to order by the President, Dr. Charles B. White. The following papers were read at the morning session: "The Contagious Diseases of Domestic Animals," by Dr. Ezra M. Hunt, of New Jersey; "Disease Among Texas Cattle," a continuation of the report made to the association at the New Orleans meeting, December, 1880, by Dr. J. R. Smith, United States Army; "A Report of the Examination of Hogs at the New Orleans Abattoir during the Summer of 1881," submitted by the New Orleans Sanitary Auxiliary Association; "Trichinæ Spiralis," by Dr. J. M. Partridge, of Indiana; "Trichinæ Spiralis in American and German Hogs," by Dr. F. S. Billings, veterinary surgeon, of Massachusetts. At the afternoon session the following were read: "The Kankakee, a Sanitary Problem in Indiana," by Prof. John L. Campbell, of Indiana; "The Comparative Vital Movements of the White and Colored Races in the United States," Dr. S. S. Herrick, of Louisiana; "The Disposal of the Dead," Dr. W. H. Curtiss, of Illinois; "The Relation of Alimentation to Infantile Development and Diseases," Dr. T. C. Duncan, of Illinois. In the evening a public reception was given at the Temple. The meeting was presided over by the Mayor. An address of welcome was delivered on the part of the city authorities by the Hon. George A. Mercer, and on behalf of the Georgia Medical Society of Savannah by Dr. R. J. Nunn. President White read his annual address. The association was afterward entertained at the residence of Dr. L. A. Tallegant.

An Outbreak of Vaccinal Syphilis is reported to have occurred at Algiers. Fifty-eight soldiers were inoculated with syphilitic vaccine lymph.

Dr. Theophilus Parvin is to be appointed to the Chair of Obstetrics and Medical and Surgical Diseases of Women in Louisville University.

Law to Prevent the Sale of Ecbolic Medicines.—A bill is before the legislature of Missouri to prevent druggists from selling ecbolic medicines without the prescription of a physician. According to the *Cincinnati Lancet and Clinic*, the bill, though aiming at a good object, goes too far.

A Homœopathic Insane Asylum.—The homœopathists of Massachusetts are making an effort to have a State asylum for the insane placed in their hands. If the experiment, when undertaken, succeeds—*similia similibus curantur.—Cincinnati Lancet and Clinic.*

Professor E. Lloyd Howard, of Baltimore, during an attack of uremic coma, recently fell into the Chesapeake Bay, and was drowned. Dr. Richard Gundry, the medical superintendent of Spring Grove Insane Asylum, near Baltimore, has been elected to fill the chair left vacant in the College of Physicians and Surgeons by the death of Professor Howard. The title of Professor Gundry's chair is Materia Medica, Therapeutics, and Mental Diseases.—*Cincinnati Lancet.*

Rabies, a Possible Cause and Probable Preventive.—This "possible cause," according to Dr. L. L. Dorr (*New York Medical Journal*), lies in the mixing of breeds. Hydrophobia may occur in all dogs, but it never originates in any but mongrels. The destruction of mongrels might stamp out the disease, only, unfortunately, no one knows exactly what dogs are of pure breed and what not. The "probable preventive" is a visit of the bitten person to the Pacific coast. No person has ever died of hydrophobia in that region, so far as is known.

Religion and Nursing.—Speaking about the character of the attendants of a sick person, Dr. J. M. Fothergill says: "A pious widow, with dyspepsia and strong religious convictions, is a ghoul when illness is about. She sucks the life out of an invalid like a moral vampire. As life ebbs she is sustained, and when the invalid has passed the portals of another world she goes away edified, strengthened, and encouraged in her murderous mission, fully prepared to extinguish the lives of any number of relatives if ill luck should prostrate them upon the sick bed."

Erythroxylon Coca in Asthma.—Four cases are reported in the *Medical and Surgical Reporter*, where coca was used with the greatest benefit in asthma.

# Original Lectures.

## THE REMOVAL OF FOREIGN BODIES FROM THE EAR.*

By D. B. ST. JOHN ROOSA, M.D., LL.D.,

PROF. OF OPHTHALMOLOGY IN THE UNIVERSITY OF THE CITY OF NEW YORK, AND OF THE EYE AND EAR IN THE UNIVERSITY OF VERMONT.

[Reported for THE MEDICAL RECORD.]

GENTLEMEN: The general practitioner is more likely to see cases of foreign bodies in the ear than is the specialist. Such cases are among the instances of every-day life. A little child at play, animated by some impulse of which adults know nothing, except when insane, will thrust such bodies as peas, beans, shoe-buttons, and the like into the auditory canal. Having once accomplished this feat, and being unable to remove the foreign body, the child often expresses anxiety and runs to its parents in great trouble. Sometimes, however, no such complaint is made, especially if the child has reached some years, and the discovery is made in the zealous efforts of mothers and nurses to clean the ears. The alarm caused by the discovery of a foreign body in the auditory canal is almost ludicrous; an alarm in the minds of the sufferer and friends, and sometimes even in the mind of the family physician. This alarm is usually entirely unnecessary. A foreign body in the auditory canal, unlike a foreign body on the cornea or in the eye, is a very harmless thing if properly treated. Even delay is not dangerous. I may venture to call your attention to a lecture upon the subject of foreign bodies in the eye, which was published in a recent number of THE MEDICAL RECORD, and you will note at once the great difference between the existence of a foreign body in the auditory canal and one in the conjunctival sac or in the cornea. It is true that a foreign body which has passed the auditory canal and entered the tympanic cavity is dangerous; but even then its danger, as regards life, is infinitesimal, if only it be left alone. The worst consequences usually are loss of the middle portion of the ear, and consequently of all acute hearing power.

There is another class of foreign bodies which may enter the auditory canal besides those already mentioned. Insects, such as the ordinary mothmiller, bed-bugs, earwigs, the ordinary house-fly, etc., are comprised in these. These enter the auditory canal without the instigation or assistance of any person, adults and children alike. I lately removed the dismembered remains of a croton-bug which had been for two years in the ear of a boy seven years old. The ear-wax had hardened around it, and it was from the symptoms produced by this mass that he sought relief. It was very difficult at first to obtain the history of an insect having entered the ear, but careful examination showed that the child had complained of his ears for a few hours about two years before, and at that time he said that something had gotten into it; but the pain passed, he ceased to speak of it, and the matter was forgotten until the remains of the bug were discovered in the plug of wax which I removed.

As I said a few moments ago, the alarm which is caused in the minds of the friends is the most striking symptom of the presence of a foreign body in the auditory canal. Let me say to you, then, at the very outset, do not be excited when a patient is brought to you who is said to have a foreign body in the ear. Let me tell you, in the second place, never to believe that there is a foreign body in the auditory canal until you have seen it with your own eyes, if you are the person who is to remove it. Take no man's, take no woman's, take no nurse's, take no person's word for this. Very bad results have occurred from the neglect of what seems to be a fundamental proposition. Ears have been syringed—much worse, have been treated with instruments; membrana tympani have been broken, ossicles have been dragged out, labyrinths have been invaded, and meningitis and death have been caused, by neglect of this simple rule. In other words, attempts have been made to remove foreign bodies from the auditory canal when there were none there. When you have time to review the literature of this subject you will find it sensational reading, and such as reflects no credit upon medical practice. Therefore, I say again, be sure that there is a foreign body in the auditory canal before you undertake to remove it. In two instances which I now remember, and I am sure there are others which I do not at this time recall, I have been summoned by competent medical men to remove foreign bodies from the auditory canal when they were not in that part, and probably never were, and I had great difficulty, in the two cases mentioned, in convincing the medical men that it was wrong to attempt to remove a thing which could not be seen. Statements of nurses and of mothers are often put beyond the testimony of one's own eyes. Now, in medicine, as I have often told you, we are to believe what we can see, what we can touch, what we can hear, and even all this with some reserve, for our deductions from what we see or think we see, from what we hear or think we hear, from what we touch or think we touch, are not always correct.

How shall we examine the auditory canal supposed to contain a foreign body? In the same manner in which we would examine it for disease of any kind—by means of the speculum and mirror. It is the method of examination which I have already described to you, and one which any competent man ought to be able to learn in five minutes. In lieu of the mirror, which may not be at hand in some instances, a piece of looking-glass answers very well; and a speculum can be easily extemporized by means of pasteboard. I speak of these things because I wish to impress upon your minds the fact that he only is a competent surgeon, he only is thoroughly at home in his profession, who can make the simplest appliances do his work. The picture of Alpheus Crosby boring the mastoid process with a gimlet, that of the surgeon amputating a leg with a jack-knife, are always very pleasant ones for the American medical profession to contemplate. They show great capabilities under difficulties.

Having once determined that there is a foreign body in the auditory canal, what are the steps for its removal? If the case has not been meddled with, your task will be sufficiently easy. If, however, the friends, in their well-meant, but unwise, efforts, have pushed the pea, or bean, or button down into the auditory canal, have lacerated the sensitive integument lining it, have broken the drumhead, have caused bleeding, and, worse than that, frightful pain, you will find your task a very difficult one. It may be diffi-

* A clinical lecture delivered in the University of Vermont.

cult because the foreign body may have been pushed beyond the canal and be imbedded in the cavity of the tympanum, and may have become impacted as the result of inflammatory action. It will also be difficult because of the restlessness and distress of the little patient. No human being who has had his ear roughly handled, even by supposed experts, will willingly consent to have it so handled again, no matter how great a reward is offered, even if he be told that to leave the foreign body there will be to endanger life.

But let us discuss the simple cases first—those in which the foreign body has been pushed in simply with the child's fingers, or where it has, as in the case of insects, entered by its own volition. What are you to do? Here we enter upon ground which, until within the last few years, I had supposed was settled. I may venture to quote myself as among the first to direct attention to this subject, in an article published in the *American Journal of Medical Science*, in 1864, and I supposed the principle had been established that the use of the syringe and warm water were the proper means for removing a foreign body from the ear. Nay, more, I had supposed it to be so well established that, in the case of any foreign body in the ear, a thorough attempt, by means of the syringe and warm water, should be made before any other measures are employed. But those of us who believe this—those of us who, as we thought, had undone the damage done by the writers of the dark ages, who attacked a foreign body as if it were a burglar, and hunted it down as if it were a fugitive from justice, have been confronted by passages in recent books from authorities on aural disease, which claim that those who use the syringe are clumsy and bunglers, and that removal by this instrument is a method never to be taught. As strong language as this has been used. But, after a careful consideration of all the aspects of the subject, I am not convinced by these recent writers. On the contrary, I think the teachings of these writers are dangerous, and that the employment of forceps, and ingenious extractors will take us back to the times of meddlesome surgery. There can be nothing more cleanly, nothing more harmless, than a stream of pure warm water, from the mouth of a syringe, directed upon a foreign body, so that the returning wave shall sweep it out; and it only needs to be fairly considered, in contradistinction to beautifully contrived forceps, admirably arranged snares, and all the other armamentarium of those who sneer at the syringe, in order to meet with your warmest approval.

If the case is one which has not been meddled with, a few uses of the syringe, without frightening the little patient, without causing any discomfort, will remove it. If, however, it has been pushed far in, or has lain long enough to swell, it will be sometimes impossible, after the most thorough trial, to remove it with the return wave of water. It will then be necessary to resort to the most careful surgical interference, and this must be done while the patient is under the influence of an anæsthetic, and the parts must be thoroughly illuminated by means of the mirror. Then it becomes an ordinary surgical procedure for the removal of a foreign body, and it is impossible to give any general rules for the performance of such a delicate operation. It is impossible to indicate beforehand what instruments should be employed. The ingenuity of man, which is sometimes as harmful as it is beneficial, has been seriously taxed in the efforts to invent instruments for the removal of foreign bodies in the ear. A very small dressing-forceps, a pair of angular forceps, and a curette will be generally found to be sufficient for any case unless it has been meddled with to such a degree as very rarely occurs. If the foreign body has been firmly impacted in the bony parts, it will then become a serious question as to how far interference should go. It scarcely falls within my province, as a teacher of the principles of aural surgery, to speak at any length upon this subject. Delay can always be safely practised, and the best surgical consultation will be needed in such cases. I am speaking to you as to general practitioners, who are to be fully armed to meet the emergencies of an ordinary practice. Such a case as one in which a foreign body has been wedged into the deeper auditory apparatus is clearly beyond the province of any general practitioner.

Paul of Ægina, in 680, reinforced by Von Tröltsch in 1864, recommended an operation for the removal of impacted foreign bodies in the ear, which has lately been performed by myself and by Dr. Orne Green, of Boston. This operation consists in the detachment of the auricle from the auditory canal. Such an operation gives very complete access to the cavity of the tympanum, and despite the objections of theoretical reviewers, it is entirely practicable. The necessary incisions heal readily, and it is by no means a formidable operation.

If you chance to be in the woods with a friend into whose ear an insect has entered, the simplest method of removing it is to pour in some water, warmed by the hand, until the insect can be dislodged. When flies and maggots gain entrance to suppurating ears, the case is one for simple treatment with the syringe, first using some agent which will kill the fly or maggot, such as carbolic acid, Labarraque's solution, or the like; after this, the stream of warm water may be employed. An attempt to remove them with the forceps only makes them more lively and increases the difficulty of their removal. Fortunately, with the advance in our knowledge as to the methods of examining and treating the ear, these cases of maggots entering a decomposing mass deep in the canal are very rare. Ancient literature, however, has much to say on this subject.*

I will now show you the proper method of syringing the ear. There is no difficulty with regard to wetting the clothing or causing any discomfort, if the following steps are taken:

In the first place, the patient should be comfortably seated. In the second place, if the patient is not old enough to hold the bowl under the ear, it should be held by some friend and well into the glenoid fossa. The first injection or two should be made very gently, and then, perhaps with more, but never with great, force. The resisting power of the drumhead is very great, as physiological experiments have shown, and there is little danger of rupturing it; but there is danger of violent syringing causing fainting and vertigo, and you should stop frequently to inquire whether or not the operation is disagreeable. In the youngest subjects, if properly done, it will be a pleasant manipulation, and, what is much better than that, it will generally be entirely successful.

In concluding what I have to say upon this subject, I venture to recapitulate. First, be sure that

* Dr. Gruening, of New York, has lately reported a case of maggots in a healthy ear, which I believe to be a unique case. Dr. Gruening will report this case in full in one of the journals.

there is a foreign body in the ear. Second, remove it by syringing, if possible. Third, wait quietly, if it is so wedged in that it cannot be removed in this manner, until you can secure competent assistance, and then proceed with care and caution, and with such instruments as your ingenuity and the ordinary instrumental collections of aural surgeons will furnish.

# Original Communications.

## ADJUVANTS, CORRIGENTS, ETC.*

By F. A. CASTLE, M.D.,
NEW YORK.

Recent writings upon the antagonism of therapeutic agents, which have been quite widely read, have greatly increased the attention given by physicians to this important subject; but while much that has been written relates to observations made with toxic doses upon animals, or upon human beings in comparative health, we have but few reliable data, as yet, that can be utilized in the treatment of disease. With all that has been written, not much has been added to our knowledge of the important class of medicines investigated by John Harley. Since his time curare, muscarin, Calabar bean, picrotoxin, etc., have been studied by the physiological pharmacodynamists, but none of these agents are commonly used as remedies, and in a case of poisoning by any one of them (a matter of no probability) the special antidote, as shown by experiments, would be hardly obtainable outside of large cities, and then only after a delay which would permit, unaided, the death or recovery of the patient.

A question of more practical importance is the influence exerted upon each other and upon the system by medicines in common use, when administered conjointly to sick persons. Belief in the value of such combination is almost as old as the art of medicine itself, but exact evidence of the nature or degree of the modification secured is notably lacking. At a period not very remote, remedies were classed according to their supposed qualities of heat, cold, moisture, or dryness, and, according to this theory of their natures, were combined with a view to augmented or otherwise modified effects. We have long since ceased to believe in the truth of this and numerous other systems equally irrational, and the result has been that, with our increasing knowledge, medical compounds have become progressively less complicated, until now it is probable that most physicians rely mainly upon simple agents. There are still, however, abundant traces of a belief in the efficacy of combination, and writers of systematic treatises upon therapeutics and the art of prescribing feel in duty bound to state that great advantages often follow the combination of active remedies; but the illustrations usually mentioned in proof of this are the mysterious properties residing in a mixture of sulphate of potash, opium, and ipecacuanha, the value of aromatics and diffusible stimulants when combined with purgatives, or of squill when given with digitalis, etc.

The tendency toward lessening the number of ingredients in medical compounds is especially noticeable in the various pharmacopœias. One substance after another has disappeared from officinal formulas, until a point has been reached at which of some it would be proper to remark—as was the case in one of the reports sent to the last Pharmacopœial Convention—that if any further pruning were contemplated, it might be as well to drop the preparation altogether.

There is especially a field for speculative thought in the multitude of formulas published in current medical literature. There is hardly a journal that does not cast these polypharmacal sops to that class of its readers who seem to treat diseases according to some system of nomenclature, and from whom the individuality of a patient and the nature of his surroundings receive but little thought. There are said to be practitioners who look upon these productions as the very essence of wisdom, and who carefully copy them into pocket-books, that they may be ready for emergencies; but it has never been thoroughly appreciated that the person who finds these formulas most serviceable is likely to be the printer, who, by omitting an ingredient now and then, makes his columns of equal length. It hazards little to presume that such modifications have but a very trifling influence upon the scientific value of many of the formulas so treated.

It must have been a practitioner of the sort here referred to who reported at a recent medical convention that he had used the following in the treatment of diphtheria:

| | |
|---|---|
| Sublimed sulphur | gr. viij. |
| Boracic acid | gr. iv. |
| Benzoic acid, | |
| Salicylic acid, | |
| Tannic acid | āā gr. j. |
| Tartaric acid. | |
| Chloride of sodium | āā gr. iv. |
| Resorcin | gr. j. |

Mix. A little to be put on the back of the tongue every hour or two.

Yet this gentleman remarked that, after treating six or seven hundred cases of diphtheria, his faith in the efficacy of drugs was very feeble.

Occasionally we hear of a prescriber who has decided views with regard to the properties of the agents that he uses, and who can give the why and wherefore for each element of his formulas, and even justify his faith on what he deems to be scientific grounds. Such, undoubtedly, was the old gentleman whose "peristaltic persuaders" were made in three layers; the outer of lunar caustic, to serve as a gastric stimulant; the intermediate one of aloes, to increase the activity of the mucous and muscular coats of the intestine, and the inner one of belladonna, the special function of which was to cause, at the proper moment, a favorable relaxation of the sphincter ani. Some special skill was required to apportion the thickness of the respective coats to the length of the patient's gut, and the old gentleman must have died before completing his original observations and publishing his tables of proportionate quantities, since no manufacturer has yet placed this marvellous pill within the reach of a constipated public.

While the accurate knowledge we possess of the manner and degree in which medicines may modify each other's action is, as has already been remarked, by no means extensive, and is only to be met with incidentally in treatises on materia medica, there appear to be a few established facts to be considered

* Read before the New York Materia Medica Society, October, 1881.

in practice; and it is reasonable to presume that if such alleged and isolated facts were gathered into available shape, and the doubtful cases duly indicated, some persons might take the trouble to verify the one or correct the other. While the importance of experiments made upon animals and healthy human beings cannot well be overestimated, it is to such *clinical* observations that we must look for practical advances in therapeutics.

It would be interesting to have a published commentary upon the formulas which from time to time have been officinal, giving the reasons that led to their adoption. Undoubtedly many of them have owed their popularity to the personal influence of their authors, while others were constructed according to some therapeutical theory prevalent at the time of their adoption. We occasionally find, however, with increased knowledge of such matters, that we are able to explain why some remedial compounds were advantageous, and we are forced to admire the acute power of observation possessed by their empirical originators.

As an instance of what follows a slight effort to trace the history of a pharmacopœial preparation, let us take the pill of aloes and myrrh. As now officinal it consists of aloes, myrrh, aromatic powder, and syrup. In the British pharmacopœia the formula more closely resembles the older ones, and contains aloes, myrrh, saffron, and confection of roses. These latter are likewise the ingredients given in the Edinburgh Pharmacopœia of 1841, and the Dublin Pharmacopœia of 1850. In the London Pharmacopœia of 1851, soft-soap and molasses took the place of confection of roses as an excipient. As long ago as 1765, John Theobald, M.D., in the sixth edition of his "New Compendious Dispensatory," gives the following description of this pill:

"Take two Ounces of Socotorine Aloes; an Ounce of Myrrh; and an Ounce of Saffron. Make them into a Mass with Syrup of Buckthorn." This Theobald calls Rufus' pill, and says of it: "This, from its Warmth to the Stomach and Bowels, and its gentle Method of Working, is deservedly ranked amongst some of our best Purgatives. It is peculiarly made use of in cold Constitutions and Indigestions; and, by greatly promoting the menstrual Discharges, will, without any other Assistance, frequently cure a Chlorosis, or the Green-Sickness. The quantity to be taken of this Mass is about Half a Dram. This Pill given in moderate Doses, viz.: four or five Grains, three times a day, will, from a Cathartic, become a very good Alterative; and, continued for some time, will compleatly relieve any obstructed habit."

Going back another century (1649), we find in Paré's treatise on "The Plague," the following:

"The pills of *Ruffus* are accounted most effectual preservatives, so that *Ruffus* himself saith that he never knew anie to be infected that used them. The composition of them is thus:

"Take of the best Aloës half a dram, of Gum *Ammoniacum*, two drachms; of Myrrh two drams and one-half, of Mastich two drachms, of Saffron seven grains: put them all together and incorporate them with the juice of Citrons, or the syrup of Limons, and make thereof a mass, and let it be kept in leather; Let the patient take the weight of half a dram evrie morning two or three hours before meat, and let him drink the water of Sorrel after it, which through its tartness and the thinness of its parts doth infringe the force and power of the malignitie or putrefaction: For experience as taught us, that Sorrel being eaten or chawed in the mouth, doth make the pricking of Scorpions unhurtful. And for those ingredients which do enter into the composition of these pills, Aloës doth cleanse and purge, Myrrh resists putrefaction, Mastich strengthens, Saffron invigorates and make's livelie the spirits that govern the bodies, especially the Vital and Animal."

Still another century earlier (1557), we find that pil. rufi was made, according to Squire, of aloes two parts; myrrh, one part; and saffron, one part: with white wine enough to make a mass.

Without going still farther back to consult the "Companion" to the Noachian medicine-chest, we will observe a notable difference in the ingredients and proportions of the formulas quoted. Paré's formula contained about one-fourth aloes, and the dose administered would give about two grains. Theobald's formula was about half aloes, and the patient would get either fifteen or two to two and a half grains, according as the purgative or alterative dose was used. The British formula contains one part in three of aloes, and the dose (five to ten grains of the whole) is about that of the earlier formulas. The virtues claimed for this pill are now by no means so important or numerous as heretofore, and a study of the separate ingredients leads to the suspicion that after all, the aloes is the only *active* one, the myrrh serving mainly to secure its subdivision in a manner that favors the action of the intestinal fluids upon it. Almost any resinous body would very likely act as well. This must also have been the only usefulness of the mastich; but how far the saffron acted as an emmenagogue, or otherwise, is still undecided, nor is it likely to be determined, in view of the fact that for many years saffron has been expensive, very liable to adulteration, rarely in the market, and but very seldom used as a medicine. The syrup of buckthorn of Theobald's formula was calculated to increase the activity of the compound, and none of the vehicles since used would appear to have been so well chosen. This is notably so in the London formula of 1851, in which soft soap was used, for Barnard S. Proctor has shown pretty conclusively that extract of aloes in combinations with caustic alkalies is oxidized and loses its bitter and purgative properties. The same observer found that an acidulous solution of aloes appeared to be less liable to change. Now, the earlier formulas for "Rufus'" pill were made with an acid vehicle—as will be seen above—a fact which the authors of the Edinburgh formula appear to have quite ignored.

I have by no means noticed all that might be said even in outline, respecting the questions raised by so hasty an examination of this one compound. A similar analysis might be made of nearly every preparation in our pharmacopœia. It is worthy of notice that little advantage has yet been taken of therapeutic facts already quite well established, to modify the formulas that yet remain officinal. The changes of late years have mainly been in the direction of uniformity in nomenclature, choice of active materials, and improvement in pharmaceutical processes. Looking through the edition now current, one observes that in the sixty (or thereabout) preparations intended for internal use, which contain adjuvants or correctents, these accessory elements are mostly carminatives or diffusible stimulants, and that their use is to improve the flavor or render the stomach or intestine more tolerant of the presence of the compound rather than to increase its effect upon the morbid state for which it is prescribed. Excepting in two or three instances the complicated formulas of the pharmacopœia are to be found among the exp-

torants and cathartics, and closer examination will show that even among these are many preparations but comparatively little used, such as confection of senna, pills of aloes and assafœtida, pills of aloes and mastic, pills of calomel, antimony, and guaiacum (or Plummer's pills), compound pills of galbanum, compound pills of squill, powder of aloes and canella, tincture of rhubarb and senna (or "compound tincture of rasins," as it has been called), troches of ipecacuanha and morphia, wine of aloes, wine of rhubarb, fluid extract of spigelia and senna, and so on. The retention of some of these relics of antiquity is probably due more to a spirit of conservatism than to a favorable appreciation of their value on the part of any considerable number of practitioners. Even the compound cathartic pill, which in time past has been thought to embrace as many of the virtues and as few of the defects of such compounds as human ingenuity could suggest, seems to be losing its hold upon professional favor, since it is not found to be a desirable formula for prolonged use, and the ingredients of which it is prepared are apt to be adulterated or deficient in strength.

One probable reason for the abandonment of these time-honored formulas is the fact that we are better able, through our knowledge of the functions of the various portions of the digestive system, to attack the source of trouble with a single corrective, or, to use an illustration somewhat hackneyed, with a rifle instead of a shot-gun. While the formulas in common use have become more simple, thus lessening the difficulty of studying the effects of their ingredients, we have gained something in the same direction by a better knowledge of the active principles of drugs, and the ability to isolate some of them without impairing their virtues.

I regret that I am not able to offer here the results of original observations upon the effects of combined remedies, and I present the following notes more as evidence of the fragmentary character of our information than because I think the facts unfamiliar. It will be hardly necessary to say that they do not embrace all the observations that have been made upon the conjoint action of remedies. Of some of them it may be doubted whether the agents used really *do* influence each other's action, and whether, as in the case of opium and subnitrate of bismuth, used together in the treatment of intestinal derangement, each does not manifest its characteristic action, its effects being superadded to those of the other.

In the literature of this subject, the writings of Dr. Harley appear to be most complete. He says, regarding the modifications caused by narcotic remedies upon each other's action:

"In medicinal doses the hypnotic effect of morphia is both increased and prolonged by atropia. When given simultaneously or previously, atropia prevents the nausea, vomiting, faintness, and insomnia caused by opium, and in doses of $\frac{1}{100}$ of atropia to $\frac{1}{4}$ gr. of morphia, atropia neutralizes the effect of opium in contracting the pupil. When given successively, the one given last, *for a short time*, counteracts the effects of the other. All the other effects of atropia are intensified by the action of morphia.

"Atropia increases the cerebral and deliriant effects of opium.

"When we find two sets of involuntary muscular fibres under the control of the cerebro-spinal and sympathetic systems, atropia will diminish the cramping and convulsive effects of opium. In other localities these effects are increased. Atropia does this through the sympathetic system, on which it is especially active. Belladonna removes the respiratory difficulty only in so far as it relaxes spasm of the bronchial tubes, and does not affect the respiratory muscles. It thus indirectly relieves over-distention of the right side of the heart, and, moreover, serves directly as a stimulant of the heart's action.

"These *local* effects are the only ones in which an antidotal action is manifest, the general effects of each being augmented by the other.

"The advantages to be gained by a combination are in cutting short the early stages of an inflammation, and the production of sleep and analgesia by opium, without its stimulant effects. It prevents the diminution of the action of the bowel, kidneys, and liver by opium.

"In the last stages of phthisis, when opium is indicated for the relief of troublesome cough, the tendency to produce sweating sometimes prevents its use. This effect can be avoided by the addition of atropia or belladonna."

The two combined may be used with great success hypodermically in chloroform anæsthesia, when the stage of excitement is shortened and much less of the anæsthetic agent rendered necessary. This latter fact is reasserted by J. M. Fothergill.

"Conium alone strongly predisposes the brain for sleep, by allaying excitement of the motor centres, and thus removing restlessness or agitation of the muscular system. Opium alone occasionally fails to procure sleep, on account of its tendency to induce or to increase existing excitement of the motor centres. This nascent tendency of opium to excite convulsive action is antagonized by conium. What is lacking in the one drug is completed by the other, and together they form a most perfect combination for bringing repose to every part of the body."

The uses of this combination are, in practice, "the facility it gives for lessening the dose of opium, and the avoidance of the uncomfortable phenomena sometimes seen in persons who are unfavorably affected by opium."

Opium and veratria appear to have a degree of antagonism when used in toxic doses, but I am aware of no published observations upon their effects when used therapeutically.

Conium and hyoscyamus act together somewhat similarly to opium and conium. "The akinesiant power of conium predisposing for the hypnotic action of henbane, while the general sedative influence of the latter assists the action of the former. Given together, the effects of the conium are first declared, and then quickly follow those of the hyoscyamus; and while the hemlock appears to accelerate the action of the henbane, the latter prolongs the influence of the conium for an hour or more beyond the usual period of its action."

A combination of opium and hyoscyamus, according to Harley, forms one of the most powerful of narcotic combinations.

Conium with belladonna behaves similarly to conium and hyoscyamus.

Caustic potash and soda decompose atropia out of the body, but, given internally, appear to have no effect on the action of belladonna. Caustic ammonia and lime-water should never be added to mixtures containing belladonna, as they completely neutralize its effects when they have remained two or three days in contact. Carbonates of the alkalies

and alkaline salts are innocuous. Acids have no particular effect on this remedy.

The study of the antagonism between belladonna and jaborandi has, as yet, produced too little in the way of therapeutic results to warrant much consideration. The same may be said of belladonna and muscaria.

Digitalis often fails to act as a diuretic until combined with bicarbonate of ammonia or with squill. Either of these adjuvants alone serves as a cardiac stimulant, and it has been claimed by numerous writers that it is only by increasing vascular tension that digitalis ever causes diuresis. Stillé is of this number, and positively asserts that, aside from this mode of action, digitalis possesses no diuretic properties. If this were so, the digitalis might, perhaps, be dispensed with, and the ammonia or squill be given alone.

In speaking of this diuretic effect of digitalis, it may be remarked that there is some ground for a belief that the diuretic principle of the drug is not soluble in alcohol, and that digitoxin, which appears to influence the action of the heart most powerfully, is not very soluble in water. Therefore, in using digitalis therapeutically, the infusion should not be chosen as a cardiac remedy, nor the alcoholic preparation when diuretic action is desired. The aromatic which is added to the infusion of digitalis serves not only to improve the taste of the tea, but also acts, perhaps, in a slight degree, as a diffusible stimulant.

It may here be observed that infusion of digitalis, if made as other infusions are not unfrequently prepared, from the fluid extract, will, as a rule, be found devoid of diuretic effect.

In formulas intended to increase vascular tension, ergot might be combined with digitalis.

None of the recent writers on the antidotal action of remedies appear to have taken note of a fact mentioned by Dr. E. R. Squibb, that inhalation of nitrous ether will cause contraction of the arterioles after paralysis of their coats by amyl nitrite, pallor of the face being one of the notable effects of inhalation of this ether.

This question of solubility, or what often amounts to the same thing, subdivision, is an extremely important one, and is not always duly considered in prescribing. As instances of this, we occasionally meet with formulas in which morphia, strychnia or arsenic are directed to be incorporated with a pill. Iodine can be given internally when in dilute solution, or finely subdivided with starch, when a corresponding dose entire of the pure substance would prove troublesome. Tannin needs usually to be given in *solid* form, owing to the difficulty of taking it otherwise, but when its styptic effect is desired, water must be given subsequently to insure its solution. In many mixtures the value of adjuvants and corrigents—or the things that have been so reputed—is, doubtless, that they serve to subdivide the active remedy and enable it to be more readily dissolved, or to extend its local effects over a wider area, and thus render it less irritant.

Brown-Séquard combines vegetable bitters with bromides as a means for maintaining the digestive functions during a long-continued use of the latter, and bicarbonate of potassium or sodium for the same purpose. A mixture of bromine salts often avoids the bromism caused by one of them. Bromides prevent or lessen the giddiness, confusion of mind, faintness, headache, and nausea often caused by opium, and increase its hypnotic effect. Arsenic given with bromides lessen their tendency to cause acne.

Iron may be given with potash when the latter is used in the alkaline treatment of gout, and by its effect in maintaining the composition of the blood avoids the destructive effects of the potassium salt upon this fluid. It has a similar effect when given with mercury, as when the latter is taken for long periods and large doses in cases of syphilis. Owing to the astringency of most of the iron salts, it is found expedient to administer with them some agent that increases intestinal secretion. Aloes is often used for this purpose, and the sulphate of potash in "Griffith's mixture" undoubtedly answers the same end. It is generally considered that the action of a laxative facilitates the constitutional effects of iron, and this may be owing to the increased supply of fluid in the intestine serving to dissolve the iron salt or albuminate, and to the lessening of vascular tissue, thus favoring absorption. Blaud's pill is practically Griffith's mixture in solid form without the myrrh, but Ringer says it acts just as well without the potash salt.

When given in combination with iron, iodine causes the iron to appear with the iodine in the saliva. This is used by Gubler as an illustration of what will be mentioned hereafter, viz., that by selecting a substance as an adjuvant which is capable of stimulating a special secretion, we may influence the escape through that channel of the remedy with which it is combined.

When camphor is administered with cantharides, the effects of the latter upon the kidneys and bladder will be more or less obviated. As camphor does not pass through the kidneys, it is possible that it forms some combination with the cantharadin which prevents its escape through that channel.

The resins of myrrh, benzoin, mastic, storax, Peru, Tolu, copaiba, guaiacum, assafœtida, jalap, scammony and gamboge, and neutral acrid principles, such as cantharadin, piperin, hydrastin, colocynthin, elaterin, and capsicin, are, with some exceptions, soluble only in the presence of alkalies. A few are also soluble in acetic acid. When, therefore, these substances, or the corresponding drugs, are introduced into the intestinal tract, with a view to their absorption into the circulation, an alkaline menstruum or excipient should be selected. In the choice of the special alkali we may gain something by choosing one whose base is excreted by the same organ that finally separates the more active remedy, or its products, from the blood. Thus, with expectorants, an ammonia salt may be given, with diuretics, potash or soda salts; the latter may well accompany the cholagogues, while magnesium salts might best be added to the gums, resins and their congeners that chiefly affect the mucous membrane of the intestine. It seems, indeed, that by a choice of adjuvants we may sometimes determine which one of two or three excretory organs a remedy may be made to most profoundly affect.

Following Dr. Ringer's observations of the effects of acids and alkalies in stimulating the flow of secretions having an opposite reaction, alkalies should be combined with bitters when taken before meals as stimulants of the appetite and of gastric secretion.

Aloes when given at meal-time is not apt to cause griping, but when so given it should be coated with some substance that will protect it until it reaches the intestine, as it is liable to disturb digestion. Owing to the fact that it requires first to be absorbed before it can produce its specific effects upon

the intestine, it is slow in action, and should not be combined with quick-acting purgatives, as in this case it would be swept out of the intestine before it had time to enter the circulation. Sulphate of iron appears to render aloes more active. Alkalies lessen considerably the activity of aloes when in contact outside the body, and the presence of an acid seems to prevent loss of strength through oxidation of the active principle. Ipecac given with aloes renders its action milder—in just what respect is not mentioned. The same is said of the aromatic oils. Hyoscyamus prevents the griping that sometimes attends the action of aloes. Alcohol renders aloes much less active than when it is given in solid form.

An extract of senna made with alcohol is quite inactive.

Podophyllin is said by eclectic practitioners to have its griping effects considerably intensified by chloride of sodium and alkalies, and lessened by lactic acid. Is this any more true of podophyllin than of other resinoid purgatives, nearly all, as we have seen, being more soluble in alkalies? Decomposition of the chloride may take place in the intestine and furnish the proper condition for increasing the solubility of the resinoid, hence its greater activity.

Jalap is said by Buchheim to act as a purgative only when combined with bile. The same is said by him of scammony, and he attributes this to the presence of soda in the bile.

Calomel in its ordinary form is insoluble, and requires either the presence of mucus, albuminoids or acids to cause its absorption. Theoretically it should not be given with chlorides, and this has led to salty food being interdicted when it is taken. This is, however, somewhat a matter of tradition.

Although the resinous purgatives are all said to act better when combined with calomel (its cholagogue effect furnishing the bile-soda for their solution), it is not desirable to employ calomel as an ingredient in a pill that needs to be repeated for some time to remove a habit of constipation.

While we cannot as yet explain satisfactorily the entire mode of action of the resinous purgatives, there is little doubt that a portion of each is absorbed and subsequently eliminated by the liver and intestinal glands, in connection with an increased intestinal secretion. We can also believe, from the "griping" that for some time precedes the escape of the intestinal contents, that the unabsorbed portion causes irritation and irregular and cramp-like peristaltic movements of the gut.

A profitable field for experiment would be the use of these substances in doses no larger than would be capable of being absorbed, triturating them with milk-sugar or some other vehicle to cause minute subdivision, combining them with alkalies to insure their ready solution and passage through the intestinal capillaries, and enveloping them in a gelatin coating to facilitate their passage through the stomach during the later stages of gastric digestion. Instead of depending on the irritant effect of undissolved resin to hasten peristaltic movements we use, instead, as an adjuvant, the saline purgatives of low diffusive power, which cause a transudation of blood-serum into the intestinal cavity, so wash out its contents. Such a combination should, if this theory of its action be correct, give us an efficient purgative unattended with disagreeable and unnecessary effects.

Sulphuret of antimony, as ordinarily administered, is uncertain and variable in its effects, the fact being that it requires an acid medium to insure its absorption.

Owing to its capacity for relaxing arterioles and increasing the secretions of all mucous membranes, ipecacuanha should be an ingredient in many cathartic compounds.

Morphia and tannic acid prevent the purgative effects of sulphate of magnesia.

Santonin is said by Küchenmeister to require the presence of an oily adjuvant to enable it to destroy ascarides.

When turpentine is given as a purgative, its irritant action is not always sufficient to secure its elimination before a sufficient amount has been absorbed to cause disturbance of other organs of the body. For this reason another purgative—such as castor-oil—should be combined with it to hasten its expulsion.

When tonics are given with purgatives, the amount of the latter required is considerably lessened.

When arsenic is given in the treatment of dartrous affections, nutritive changes are more rapid when the intestinal secretions are stimulated by laxatives.

Chloral is apt to cause paralysis of the muscular coat of the arterioles. This may be avoided, in a measure, while its hypnotic effect remains, by giving strychnine or belladonna with it. Its hypnotic effect is increased by the addition of the bromides, or small doses of morphia.

This is likewise true of all the narcotics which individually act on different portions of the nervous system (as opium, belladonna, ether, and hydrocyanic acid), since they produce better effects when combined than when used singly, and the relative size of the dose required is smaller.

Bartholow recommends chloral in the second stage of inflammations, to reduce the temperature, quiet restlessness and delirium, and dissolve the exudations. To avoid its paralyzing effect upon a weak heart, small doses, not repeated more often than every two hours, should be accompanied with atropia, which sustains the heart's action and does not interfere with the other effects of the chloral.

Strychnia has been found by Fothergill to serve as a respiratory stimulant in dyspnœa caused by opium. In a case of renal disease, in which strychnia was employed as a respiratory stimulant, and in which œdema of the legs supervened, the latter disappeared upon the addition of digitalis. Ammonia serves also as a respiratory stimulant, and when combined with opium, prevents the dyspnœa sometimes caused by the latter.

Chloral has been found to be an antidote to the toxic effects of strychnia, but I have yet to know of any experience derived from their use therapeutically, in which the chloral was employed as a corrective of the other.

Strychnia may be added to expectorant remedies when it is desired to increase the activity of the respiratory function. It is also serviceable in chloroform anæsthesia to prevent failure of the respiration or circulation, and may well be administered hypodermically before the inhalation of chloroform.

When potassic salts are required in full doses, their depressant effect upon the heart can be greatly obviated by strychnia or digitalis. This is especially the case in gout with dilated heart.

Gaillard says that ammonia, occasionally administered by inhalation during chloroform-anæsthesia, prevents heart-failure. Alcohol has frequently been

administered before an operation for the same purpose.

Another instance of the value of combination, is the recent demonstration, by members of the New York Therapeutical Society, of the value of sulphuric ether as a corrigent for cod-liver oil when internally administered.

Carbonate or spirit of ammonia, given with iodide of potassium, are said to control the symptoms of iodism in some cases.

Opium renders iodide of potassium inert.

The effects of quinine are said to be counteracted by diffusible stimulants, but whether all of its effects are so antidoted (which is hardly probable, as we know of no substance which is a perfect antidote for any other) is not generally stated. Hydrobromic acid and bromide of potassium, we are now well aware, lessen the cerebral symptoms of cinchonism, and to some extent lessen other disturbances of the nervous system by this agent.

Alkalinity favors the absorption of arsenious acid and of salts having alkaline bases, or which are made insoluble by acids.

In the administration of many remedies, it is desirable to secure a diminution of arterial tension before their absorption can take place, and this is usually effected by stimulating the excretions; thus, a purgative is given before quinine and during the continued use of iron, arsenic, iodine, antimony, etc.

I have made but little attempt to classify the observations above enumerated, and well appreciate that I have failed to do such justice to the subject as its merits demand. If such classification and analysis as is quite possible should be made of these and similar statements, it might, I think, be shown that in most cases absorption, vascular tension, activity of the nerve-centres which control respiration, circulation, and secretion, and those more subtle changes which go on in the ultimate structure of tissues, and which are modified by the presence in them of therapeutic agents, are the conditions which are chiefly controlled by remedies administered conjointly; that the ways in which remedies modify *each other* are physical rather than vital, and are, as a rule, manifested previous to their entry into the circulation; that we know as yet very little that is reliable about the modes or degrees in which remedies administered together affect vital functions in a manner not possible to either when administered singly; that the only real advance in this direction has been through the study of individual remedies and a thorough acquaintance with their properties before administering them in combination; and that, generally, the possession of pure and active medicines, in suitable form for administration, is of far greater importance than any effect that is likely to result from such combination. When our medicinal agents shall be chosen and prepared in such manner that each possesses uniform activity, we may be able, in most cases, to graduate the amount used, so that no corrigents will be required to prevent excessive and undesirable effects. The nature of a disease being comprehended, we shall then apply our remedies for the relief of its symptoms, or the modification of its results, better than we can now hope to do with drugs about which we know little, in combinations about which we know less.

NEW YORK, October, 1881.

THE AMERICAN JOURNAL OF OBSTETRICS will, after January, 1882, issue a monthly supplement.

## HYDRANGEA IN RENAL CALCULUS.

By BENJAMIN EDSON, M.D.,

BROOKLYN, N. Y.

ATTACKS of nephritic colic may generally be alleviated by the use of relaxants and anodynes, but the peculiar conditions of the system that determine the renal deposits may continue for years, or indefinitely, despite the most approved rational treatment. Frequently serious lesions of the kidney are produced, and life is thus sometimes shortened.

The uncertainty, not to say failure, that often attends the treatment of these cases will warrant the presentation of the history of a single case, in which the use of hydrangea was attended with results highly encouraging.

About three years since, Mr. M. A——, thirty-three years of age, of full and robust habit, came under my care for an attack of renal colic. By means of the hot bath, and the free use of morphia, that particular attack was in due time alleviated.

I learned that for nearly four years he had suffered at varying intervals from this trouble. Sometimes he had but a single attack in a month or two, but more commonly he had them as often as once a week. Their ordinary duration was perhaps from two to six hours, but they sometimes lasted for twenty-four hours or even longer. That they were severe may be judged by the fact that the patient sometimes fainted from the excruciating pain. The deposits were of the uric acid variety. The urine at various times contained blood, mucus, and muco-pus.

He had been under the care of reputable physicians, who had prescribed the standard remedies usual in such cases. Under their treatment, however, little if any relief had been afforded. There seemed to be but little more for me to do than to go over about the same ground. I did so, using freely the vegetable potassium salts, and paying considerable attention to his habits and diet, particularly prohibiting the excessive use of saccharine substances to which he had always been addicted. After having him under observation for more than a year, I could not discover any diminution in either the frequency or the severity of his attacks.

In the early part of last year I saw reported two cases of renal calculus successfully treated with hydrangea arborescens. My impression is that these cases occurred either in Georgia or Alabama, but just where they were reported I cannot now tell.*

In May, 1880, Mr. A. was suffering from attacks of renal colic as often as once in a week or ten days. I then put him upon fluid extract of hydrangea, ℥j, t. i. d. The result was as gratifying as it was unexpected. For the next eleven months he had but a single attack. The genito-urinary troubles also improved in a marked degree.

In April last, considering himself well, giving up the use of the drug, and probably becoming less prudent in his habits, he had two or three slight attacks of his former trouble. He has since been taking the drug, and has been free from any further attacks of renal colic.

How long he will be compelled to continue the medicine, and whether he will be permanently relieved so as to forego its use altogether, I cannot predict with any degree of certainty. That the drug has exerted a marked control over the disease is beyond question.

Whether its remedial action consists chiefly in its

* *Vide* cases of Dr. E. B. Freeman, of Barton, Ala., MEDICAL RECORD, vol. xvii., p. 471.—ED.

increasing the amount of urine secreted, or whether its presence determines the proper oxidation of the waste products, I am not prepared to say. Nor would it be wise to assume that the drug will always act thus favorably, nor, perhaps, equally well in the case of oxalate and phosphatic deposits.

In addition to the two cases already referred to, I simply give this case for what it may be clinically worth.

## UNDEVELOPED UTERUS WITH APPARENT ABSENCE OF OVARIES.

By EMMA WARD EDWARDS, M.D.,
NEWARK, N. J.

L. S——; single; aged thirty-nine; American; height, five feet three inches; weight, about one hundred and fifty pounds; with exception of slight paleness, quite healthy in appearance. On November 1st applied to me for a certificate of health, in order to procure a life insurance policy. Stated she had never needed the services of a physician but once during her life. Nine years ago she had been ill with gastric fever. Heart and lungs were normal. In the course of the examination questions elicited the fact that she had never menstruated. She made no objection to an examination of the pelvic organs, nor did she appear curious to know in what way she was unlike others of her sex.

The mammary glands were very slightly developed.

The external organs of generation were like those of a girl when the first signs of puberty are seen.

The vagina was remarkably long aad capacious for a virginal one. The rugæ nearly absent. No hymen nor evidence of one having existed. At first I could find no uterus, but finally discovered a very light and movable body about the size of a lady's thimble. Nothing like a cervix could be felt in the vagina, nor indication of an os uteri. As far as could be ascertained, no ovaries were present. There is not, nor seems ever to have been, any menstrual molimen. One of the most striking features of her case was her complete indifference to her menstrual condition. She casually remarked she supposed she was the one-hundredth woman.

Upon inquiring her meaning, she told me she understood that every hundredth woman did not menstruate and every hundredth man did. Have any of your readers heard of this remarkable popular notion?

**Punishment in the Medical Department of the Navy.**—The following account of an unpleasantness in the navy, is given by the *Nautical Gazette:* A big bully of a passed assistant surgeon recently cursed and menaced a little meek passed assistant surgeon, which resulted in the court-martial of the former; the sentence of the court was that the big bully be suspended from duty for three months and be reprimanded by the Secretary of the Navy. The suspension from duty is equivalent to a leave of absence for that period, without pay, and the reprimand was, we should say, more of a punishment for the Secretary to write than for the surgeon to receive. While the bully is enjoying his leave, the meek little surgeon has been ordered to shore duty at Nagasaki. This kind of administration of the Navy may be expected to revive the code among its officers.

## ALCOHOL IN THERAPEUTICS.

By LEWIS D. MASON, M.D.,
FORT HAMILTON, N. Y.

In a course of addresses on "Abstinence," delivered before the Hunterian Society of London, in 1878, Dr. Benjamin W. Richardson uses these words in referring to the difficulties that surround the use of alcohol in general medical practice: "But prescribe it as a medicine; do not permit its use as a beverage. Prescribe it as alcohol from the dispensary. Learn the exact quantity that is required to produce the desired effect, and then you will discover, and in no other way, whether the good attributed to the grog is due to the alcohol it contains, or to some other agency." This is the scientific, and, as I think, the common sense mode of procedure.

Dr. Richardson prefers the methylic or lighter spirit to the ethylic, and finds that it gives better results than the latter. He suggests that physicians, in many instances, might follow his practice with advantage. The advantages of the methylic alcohol are, in his opinion, its more rapid action and a much less prolonged effect than is the case with common alcohol, so that it produces its effect promptly, and, what is of most importance, it demands the least possible ultimate expenditure of animal force for its elimination from the body.

Dr. Richardson sounded the key note when he advocated the use of alcohol in medical practice in lieu of beer, wine, whiskey, and other liquors containing alcohol. Within the past two years the medical officers of the Inebriates' Home, at Fort Hamilton, N. Y., have recognized the value of Dr. Richardson's suggestions, and adopted them in the treatment of the various forms of alcoholism, when the use of alcohol was indicated, and have found the following benefits to proceed from their adoption:

*First.*—The satisfaction of having a solution containing a definite percentage of alcohol, thus providing an exact system of dosage.

*Second.*—A very marked saving, and, therefore, a method of value from an economical point alone, especially in those institutions where the liquor-bill is a large item of expense.

*Third.*—The moral effect on the patient, in compelling him to at once break off his accustomed stimulant and providing a "medicine" as an efficient substitute.

*Fourth.*—The advantage which the alcohol has over brandy, whiskey, etc., is that, owing to accuracy and concentration of the dosage, the patient convalesces in one-half the time and with less suffering.

In the annual report for 1880 of the Asylum for the Insane, London, Canada, Dr. R. M. Bucke, superintendent says: "No beer, wine, whiskey, or brandy has been used in this asylum during the last twelve months. In place of these, in certain cases of illness where alcohol appeared to be indicated, we have given this in its pure form—mixed, of course, with water, as other medicines are. In this way we have consumed, in the course of the year, four gallons, six pints, and fifteen ounces of alcohol, equal to about nine gallons of whiskey, or one gallon of whiskey to every one hundred patients under treatment, as against (in former years) three hundred dollars' worth of beer, wine, and whiskey to every one hundred patients treated.

Another advantage which this method of prescribing alcohol possesses is the lesson which the

community will receive in a quiet way, that the proper place for alcohol in any of its forms or combinations is the shelf of the pharmacist.

Moreover, in a properly compounded prescription containing alcohol, the physician will have a much greater control of the future physical and moral welfare of his patient, than if he directed him simply to take alcohol as contained in one of the various forms of liquor in common use.

It may be added that Dr. Norman Kerr and other London physicians of eminence have indorsed and adopted the plan of Richardson, and the quotation from the report of the asylum in Canada shows that the method is being adopted in other institutions besides the Inebriates' Home at Fort Hamilton.

We may further note that it is necessary the alcohol should be disguised by the addition of the various carminatives or bitter tonics, and also colored by caramel, so that the patient may not be unnecessarily informed as to what he is taking.

We use what we term our "absolute mixture" in treating patients, as a rule, and without their knowledge as to the fact they are taking alcohol.

We further find that the ninety-five per cent. alcohol is equally as efficient as the absolute, which we formerly used, and which was more expensive.

## Progress of Medical Science.

CLINICAL RESEARCHES ON THE CEPHALIC SOUFFLE OF ADULTS, BY DR. TRIPIER.—"Auscultation of the head," says the author, "has not entered into practice, because of the contradictory results to which its study has led, and by reason of the paucity of useful knowledge until this day derived from it. This remark is particularly applicable to the researches concerning the cephalic souffle, the most important phenomenon furnished by this mode of exploration. I have had occasion to observe this souffle a certain number of times, and it has appeared to me to be worthy of the physician's attention." Dr. Tripier then alludes to the observations of various writers, beginning with those of Fisher, of Boston, who first described the cephalic bruit in 1833. As a result of his own researches, he presents these facts: The cephalic souffle is observed in adults, as has been stated by Fisher and Whitney, and denied by Roger, whose opinion is generally accepted at the present time. I have observed it in a case of anæmia from metrorrhagia, in several chlorotics, in a patient suffering from cachectic anæmia, in a case of intracranial tumor, and in one of hydrocephalus. It is a profound systolic souffle heard all over the cranium, and principally at the sides, at the level of the temples, its maximum intensity being in the right temporal region. It is not modified by changing the position of the head or trunk. Patients who present this phenomenon hear an intermittent bruit synchronous with the souffle perceived on auscultation, and consequently synchronous with the cardiac systole. The intensity of the bruit is proportionate to that of the cephalic souffle. The cephalic souffle may diminish and disappear under a cure or an aggravation of the malady. The cephalic souffle, perfectly synchronous with the cardiac systole, takes place in the arterial system. It is not produced by the transmission of the systolic souffle of the heart, noticed in chlorotic and anæmic patients, nor by the transmission of a souffle produced in the arteries or veins of the neck. By a process of exclusion we locate it in the terminal portion of the internal carotid artery, at the level of the spot where it penetrates into the cranial cavity. Not only are there many arguments in favor of this hypothesis, but in one instance there was located upon the artery in this situation a small tumor, which gave rise to a bruit similar to that perceived in other cases. The souffle may be produced on both sides, or perhaps only on one, preferably the right. In hemorrhagic and cachectic anæmia, as well as in chlorosis, when the anæmic symptoms are intense and of long duration, notably when there exists pronounced discoloration of the tegumentary structures, palpitation and dyspnœa upon the least effort, digestive disturbances, vomiting, and loss of power, the cephalic souffle is met with. In these cases there was a cardiac systolic souffle, which was absent in intracranial lesions. The cephalic souffle without a souffle at the base of the heart, and especially without anæmia, implies a probable compression of the internal carotid, at the level of its terminal portion, when there is no orbital trouble. A distinction must be made between the cephalic souffle heard in the preceding cases and the continuous reinforced souffle produced by a communication of the internal carotid with the cavernous sinus; we must also differentiate between the former and the intermittent souffle to which aneurisms of the carotid and the ophthalmic give rise. The souffle is accompanied by characteristic orbital signs in these cases of aneurism and arterio-venous communication. We have not found the cephalic souffle in any of the cerebral affections mentioned by Fisher and Whitney, except hydrocephalus. We have not met with it in the healthy adult. We have not met with a continuous cephalic souffle in adults. Patients may hear what are probably continuous or intermittent venous bruits; these are not to be confounded with those accompanying the cephalic souffle. The cephalic souffle may furnish indications diagnostically, prognostically, and therapeutically valuable in the diseases in which it is present.—*Rev. de Méd.*, February, 1881.

THE ACTION OF HYOSCYAMINE AND ITS THERAPEUTICAL VALUE IN DISEASES OF THE MIND.—A treatise upon this subject by Drs. Seppilli and Riva concludes with the following *résumé*: Hyoscyamine has an indisputable sedative and hypnotic action, but is nevertheless, not to be preferred to certain other substances of similar virtues, on account of the inconvenience attending its prolonged use. Of all forms of mental diseases, recurrent mania is one in which hyoscyamine is of some advantage. Given in time, when the prodromata begin to appear, it succeeds, if not in averting the attack, at least in mitigating the following ones:

Hyoscyamine sometimes diminishes the intensity of epilectic seizures, and lessens the frequency of their appearance.

Considering the facility of its administration, its hypodermic injection giving rise to no cutaneous trouble, the certainty and promptitude of its action, it is of special advantage in cases where patients refuse to take chloral by the mouth, and in which the administration of this drug per rectum is impossible on account of the condition of the gut or the struggle of the patient. Hyoscyamine is indicated when very excited and clamorous subjects are to be conducted from their residences

to an asylum, and a certain and efficacious remedy is needed to produce calm in the shortest possible space of time, that the transport may be rendered less difficult, supervision less dangerous, and measures of coercion, which only irritate the patient more, unnecessary.

The dose ordinarily adopted by the authors, was 0.005 to 0.01 gramme (gr. $\frac{1}{12}$ to $\frac{1}{6}$) once a day. In several cases of chronic mania and violent dementia, in order to produce calm, they administer, three times a day (8 A.M., 4 P.M., 10 P.M.), from 0.004 to 0.005 gramme (gr. $\frac{1}{15}$ to $\frac{1}{12}$). In two cases of chronic mania, as much as 0.003 gramme (gr. $\frac{1}{2}$), divided into three injections, was given during the day. In beginning the treatment with this remedy, small doses, 0.002 to 0.004 gramme (gr. $\frac{1}{30}$ to $\frac{1}{15}$), were employed in order to ascertain the degree of tolerance.

DELPHINIUM AJACIS.—Dr. Benvenuti has published the results of his researches upon the virtues of delphinium ajacis. A cold acetic acid infusion of the flowers in many cases of phtheiriasis pubis was very efficient in destroying parasites and ova. In several examples of intractable ulcerating bubo, lint soaked with the above infusion brought about speedy cicatrization. An aqueous infusion of the dried flowers brought about similar results in instances of phagedenic ulcers, virulent wounds, and adenites seen in prostitutes. From his experiments, the author draws the following conclusions: The flowers of the delphinium possess an insecticide action. They are to be preferred to other remedies of similar action on account of cheapness and absence of smell; they have a marked anæsthetic action, are excitant, possess a rubefacient action, are astringent, and antizymotic. The author thinks this remedy has many points of resemblance with carbolic acid and iodoform.—*Giorn. Ital. delle mal. Ven. e della Pelle.*, August, 1881.

A FORM OF GONORRHŒAL ARTHRITIS HITHERTO IMPERFECTLY DESCRIBED.—Diverse opinions are held by observers on the subject of gonorrhœal arthritis. According to Ricord, this malady manifests itself as a hydrarthrosis. It is, as a rule, monarticular, and in cases where several joints are involved simultaneously or successively, there is always one, preferably the knee, where the lesions are most pronounced and characteristic. The disease is accompanied by pains, which may be very marked, but are less so than in ordinary acute rheumatism. The affected joint becomes tumefied, and it is easily seen that this tumefaction is not due to any swelling of the osseous extremities, the ligaments, or periarticular soft parts, but to synovial effusion. Besides these ordinary cases, there are some in which other constituent parts of the joint than the synovial membrane are also affected and manifest signs of inflammation. This opinion is identical with that of Rollet. Adding to this what Ricord and Rollet regard as characteristics of gonorrhœal rheumatism—the affection of the same joint in the majority of cases, and the more pronounced slowness of evolution of the local manifestations—it is easy to recognize in their description two of the forms of gonorrhœal rheumatism described by Fournier, the hydrarthrotic and the arthritic. According to Fournier, hydrarthrosis is less frequent than it is generally supposed to be, the arthritic form being the one most often met with. This latter resembles in its articular manifestations common acute or subacute rheumatism. It is clinically characterized by a generally slight swelling of several joints, often so slight as to be hardly apparent, by pain more or less intense at the beginning, but soon moderating, and more markedly so than in common rheumatism, and especially by slightly marked general symptoms, which are in proportion to the articular fluxions. This form is susceptible of varying degrees; in some instances the symptoms may be very mild; in others, and this is a fact ignored by older writers, the disease may assume an intensity equal to that of a veritable arthritis, being accompanied by great swelling, intense heat, extreme pain, and burning fever; *all these, however, moderating at the end of a few days.* These latter cases Fournier regards as exceptional, but the authors, MM. Duplay and Brun, having seen a large number of them, believe themselves justified in asserting that such cases have hitherto been regarded as exceptional, because they were misunderstood, and their symptoms and general course have not appeared to differ in a manner sufficiently marked from ordinary rheumatic arthritis to merit a special description. The observations of Duplay and Brun also confirm the conclusions of Fournier, upon which writers, however, do not sufficiently insist, viz., that gonorrhœal arthritis may, in females, as well as in males, be complicated by rheumatic accidents, not exceptionally, but commonly; that contrary opinions held theretofore were due to the fact that observations had not been conducted in the right direction. The authors do not agree with Fourestié's assertion that the acuteness of the articular lesions corresponds with the acuteness of the gonorrhœa. As to the locality preferably affected by acute gonorrhœal arthritis, facts were not collected in sufficient number to warrant a definite assertion; no articulation, however, is free from liability. Exceptionally arthritis appears suddenly in its most acute form during a condition of general health, unimpaired even by the gonorrhœa; it may succeed a traumatism, and appear to be developed under its influence. More frequently, however, it is preceded by morbid manifestations whose evolution may, so to speak, be regarded as a true period of invasion. These morbid manifestations consist in a feeling of general malaise, loss of appetite, a light febrile movement, and particularly vague, transitory, shifting pains. Among the local symptoms, pain is the first in the order of time; it is very acute, and remains so until proper therapeutic measures are instituted. During the night it may be intense enough to prevent sleep. Besides this form of pain there is another variety, which may be provoked by pressure and motion. Tumefaction soon follows pain, and with it come deformity of the member, modifications in the condition of the periarticular tissues, and changes in the color and temperature of the integument. However pronounced the swelling may be, it is due, in a very great measure, if not altogether, to infiltration of the periarticular structures. In the centre of an œdematous empâtement the finger sometimes appreciates a pseudo-fluctuation, which may give rise to the mistaken idea of a purulent collection.

In patients who have suffered from this form of gonorrhœal arthritis for some time without having had rational treatment, the least movement of the joint gives rise to a rubbing, crackling sound, which leads one to doubt the absolute integrity of the articular cartilages. The rapid disintegration of the principal elements of the joints constitutes one of the characteristics of this variety of arthritis, when it is treated badly or not at all. In this respect the course of the disease contrasts strangely with the

simple phenomena noticed when rational procedures are instituted from the beginning. Treatment consists in absolute immobilization of the entire segment of the limb corresponding to the joint affected; this is to be accomplished, not by means of splints or the simple gutter, but by a solid plaster apparatus. The course of the disease is thus greatly modified. In the large majority of cases the spontaneous pain disappears on the day of application of the apparatus; the œdema rapidly undergoes an appreciable diminution, but the infiltration and the empâtement disappear slowly. In favorable cases, and this class includes a large number of those in which immobilization has been practised from the outset, the joint returns almost immediately to its normal condition after removal of the apparatus. Cases that have been badly treated, or not at all, often end in anchylosis.

In some instances, however, the issue is unfavorable in spite of most careful treatment. It was for this reason that Gosselin applied the name *plastic anchylosing arthritis* to gonorrhœal arthritis.—*Archives Générales de Médecine*, May, 1881.

THE RESOLUTION OF NEOPLASTIC TUMORS.—Dr. Gherardo Ferrari, relating the history of a myxomatous lipoma of the neck operated upon by him, stated that the irritant action of vesicants, tincture of iodine, etc., erroneously prescribed as resolvents in the early stages of neoplastic tumors, served to increase the activity of cellular proliferation and new formation of vessels in such a manner as to cause a more rapid development of the tumor. Even medicine is too much the slave of fashion, and iodine, at present almost regarded as a universal panacea, is employed in innumerable morbid conditions, sometimes doing good, sometimes working absolute mischief. The effects of iodine are very different, according as it is given in large or small doses, or for long or short periods of time. Iodine acts as a solvent, favors metamorphosis, and accelerates the consumption and elimination of those materials which, in normal and pathological tissues, represent a *caput mortuum*. In small doses it increases the secretion of the peptic and intestinal glands; in large doses, however, it favors a decrease of bodily weight, reduces hyperplasia and chronic glandular hypertrophy, and causes atrophy of the mammæ, the ovaries, the testicles, and (according to Cantani) the thyroid gland.—*Lo Sperimentale* and *Racog. Med.*, July, 1881.

NEW DISTINCTION BETWEEN HYDRURIA AND SIMPLE POLYURIA.—In the case of an individual affected for five or six years with polydipsia and exaggerated secretion of urine (with the usual run of concomitant symptoms), Professor Concato makes a new and important distinction between simple polyuria and hydruria. This distinction was suggested by the following data obtained from examination of the patient's urine: Quantity, four and one-half litres; specific gravity, 1009; lemon-colored and transparent; reaction, acid; no sediment; urea, 5.47 per cent.; chlorides, seven per cent.; no albumen; no sugar; pigment matter, sulphates, and phosphates in small quantity. Here the amount of water was increased, the quantity of organic and inorganic materials remaining normal; in polyuria, however, besides an increase in the amount of water, the quantity of organic and inorganic components is also increased. Polyuria represents a more general lesion than hydruria; in the former there is increased filtration through Bowman's capsule and the tubuli contorti; in the latter, increased filtration through Bowman's capsule alone. The treatment was directed toward giving tonicity to the renal vessels by means of the nervous system, and consisted, 1st, in the use of atropine in quantities of 1 to 3 milligr. ($\frac{1}{64}$ to $\frac{1}{20}$ grain) a day, together with valerian (to quench the thirst) and chloral to overcome insomnia, the only result attained; 2d, in an exclusively animal diet with the infusion of cocoa and the tincture of nux vomica (this was unsuccessful); 3d, in the use of electricity, the + pole being placed over the middle of the lumbar portion of the cord, and the — pole on the abdominal wall from the middle line to the right and left kidney respectively. This last procedure was followed by a progressive diminution in the amount of urine, the quantity falling from 3,500 c.c. to 1,300 c.c. Its specific gravity rose to 1021; and the percentage of urea rose to 22.28. Thirst was diminished, the patient drinking only one litre, 700 c.c. of liquor a day; he gained 3 kilogr. in weight. The author concludes that although these prompt and happy effects cannot absolutely be demonstrated as results of the electricity, yet relief followed immediately upon application of the galvanic current.—*Gazz. delle Clin. and Recog. Medico*, July, 1881.

PERMANGANATE OF POTASSIUM IN SERPENTS' BITES.—From a series of experiments made by himself, M. de Lacerda (*La France Médicale*, September 25, 1881) concludes that the permanganate of potassium acts as a true antidote against the poison of serpents. The venom was received upon cotton, dissolved in a small quantity of water, and introduced hypodermically into the cellular tissue of dogs. In one set of cases this injection was followed a minute or two after by one of an equal quantity of a filtered solution of the permanganate (1-100). The next day the animals presented no local lesions; at the utmost there was a slight tumefaction at the point of puncture, but no infiltration or irritation. In another set no permanganate was employed. In these instances the injection of the venom was always followed by great local tumefactions, abscesses of larger or smaller size, loss of substance, and destruction of tissue. The permanganate injected into the veins also acts as an antidote in cases of serpents' venom introduced into the venous system. Injected half a minute after the introduction of the poison, the permanganate prevented the development of toxic symptoms; injected when such symptoms were already manifested, it caused them to disappear. In those instances where no antidote was used the animals died.

PARACENTESIS OF THE PERICARDIUM.—According to Severi, paracentesis of the pericardium is indicated in simple or rheumatic effusions, seven out of ten operations resulting favorably. When the life of a patient is endangered by the presence of fluid, this operation should be performed, although the pericarditis may be tubercular, associated with chronic pulmonary affections, or with some bloody effusion. Operative interference is emphatically indicated when there is pus in the sac. Pericardial paracentesis is a measure of some gravity, but many of the accidents formerly experienced by physicians are now avoided through the introduction of improved instruments and better methods of operating. Though a palliative measure, which may have to be performed several times, it leads, in some instances, to a radical cure.—*Lo Sperimentale*, April, 1881.

TREATMENT OF ACUTE ARTICULAR RHEUMATISM.—Dr. Carpani divides the methods of treating this affection into four groups: 1st, with salicylate of soda; 2d, with quinine; 3d, with benzoic acid; 4th, with the application of vesicants *loco dolenti*. He lays down the following maxims: 1, the salicylate is of value in case of acute febrile polyarthritis with marked articular manifestations, unless it be contra-indicated by concomitant cardiac affections, nervous, gastro-intestinal, or renal troubles; 2, the bisulphate of quinine is to be employed when rheumatism is associated with or dependent upon malarial poisoning; 3, benzoic acid is efficacious in cases of acute febrile articular rheumatism, complicated by nephritis; 4, vesicants (Dechilli's and Davies' method) are certain to cure rheumatism affecting one or only a few joints.—*Annali Universali* and *Racog. Med.*, July, 1881.

INTERMISSIONS OF THE PULSE, SYNCOPE, AND SUDDEN DEATH IN TYPHOID FEVER.—In a treatise on the above subject, reprinted from the *Union Méd. et Scien. du Nord-Est*, Dr. Langlet draws the following conclusions:

In typhoid fever, during the period extending from the first week of convalescence to the middle of this stage, intermissions of the pulse are frequently observed. These do not appear to be in constant ratio with the intensity of the muscular lesions of the heart, and may be considered as accidents of cardiac innervation and of encephalic origin. They often lead to more or less grave syncopal attacks, from which the patient may entirely recover. These attacks of syncope, provoked by sudden movements or violent emotion, if prolonged, may prove fatal.

Intermissions of the pulse, without being the only factor in cases of sudden death in typhoid fever, seem to play a great rôle, and demand the attention of the practitioner, that he may be upon his guard to ward off grave accidents.

PULMONARY PHTHISIS AND MENSTRUATION.—Daremberg believes that the menstrual function has considerable influence over pulmonary phthisis. According to him, menstruation is now and then the cause of phthisis—that is to say, in women who become consumptive upon cessation of the menstrual flow. When pulmonary changes exist, the menstrual function may induce congestions either around the focus of the lesion, or in a healthy part of the lung; there may be hemorrhage or inflammation. When the catamenial discharges are suppressed while ovarian excitement remains, these congestions may become very intense and grave. If the flow persists after the cessation of ovulation, anæmia instead of reflex congestions results. When both the ovarian and the uterine functions have ceased, reflex and pulmonary congestions are not to be feared. After parturition, similar congestions of the lung are to be apprehended. Sudden suppression of the menses does not *per se* give rise to tuberculosis, but may contribute to its development in women predisposed to this disease. The lungs of phthisical women should be carefully examined at each menstrual epoch, and any nervous or vital excitation should be combated by the moderate exhibition of digitalis, bromide of potassium, and quinine, by absolute rest, and by the use of revulsives (vesicants, croton-oil, inunctions, etc.). If the menstrual flow ceases, though the ovarian function continues, the same therapeutical measures are indicated, besides friction, cold baths, etc., and if this do not suffice, in addition, purgatives, emmenagogues, excitants, such as alcohol and ammonium acetate; stimulants like rue, savine, aloes, uva ursi, apiol, and ergotine, borax, and tonics such as strychnia and quinine. By this treatment the menstrual flow is made to appear again in the greater number of cases. When the uterine function continues after cessation of that of the ovaries, the flow should be lessened gradually, as a sudden considerable diminution would be productive of evil. When both functions have ceased, it is worse than useless to attempt to again bring on the menses. When, after a long absence, the menstrual discharge again appears, without a great local or general improvement, caution is necessary in framing a favorable prognosis, because such an apparent return of the menses often indicates grave disturbances of the circulation, and is the forerunner of serious phenomena.—*Lo Sperimentale*, April, 1881.

DIABETES AND AFFECTIONS OF THE PANCREAS.—In 1877, Lancereaux found that certain forms of diabetes mellitus were associated with lesions of the pancreas. In these cases the malady began suddenly, ran a rapid course, with marked emaciation, polydipsia, polyphagia, and peculiar alvine dejections. Depierre found that various pancreatic lesions may be regarded as causes of this form of glycosuria. These lesions may be primary, or they may be secondary to the presence of calculi, or to the obstruction of the ducts by neoplasms. In these cases there seems to be a complete abrogation of the pancreatic function, and this abolition is indicated by a train of especial symptoms, constituting emaciating diabetes, a form very different from that of ordinary polyuria in its clinical aspect. In the latter there is an initial stage of apparent health which renders the progress of the disease slow and insidious; in pancreatic diabetes, however, in the midst of a general ill-health, the first symptoms appear, consisting, usually, in grave intestinal manifestations, vertigo, vomiting, and icterus. These symptoms soon disappear, but leave the patient in a state of extreme debility, and are soon followed by the true symptoms of the disease, which latter may also arise without being preceded by those mentioned. These phenomena are polydipsia, polyphagia, polyuria, and antophagism; they reach their climax in a few weeks or months, and are very characteristic of this form of glycosuria. Generally there is diarrhœa, and the urine contains a large amount of sugar. A frequent complication of this disease is pulmonary phthisis, together with an emaciation of such extreme rapidity that in a few months the patient loses successively his physical, intellectual, and virile powers. To this complete prostration and marasmus are added a hectic fever and symptoms of consumption. The disease generally runs its course in half a year, but it may extend over a year and a half to three years. The fatty, creamy fæces are met with in this malady, but it is to be remembered that they are also to be found in other pathological conditions of the organ. A point of diagnostic value, is the deficient digestion of nitrogenized substances, in cases of atrophy of the pancreas; shreds of undigested muscular tissue are found in the fæces of the patient. Besides the ordinary remedies for diabetes mellitis, pancreatine should be administered in these cases, in order to supply the deficiency of pancreatic juice, and thus aid digestion.—*Lo Sperimentale*, April, 1881.

## OUR RELATIONS WITH THE PUBLIC.

THE relations which the profession have sustained to the public, particularly during the last few months, in connection with the case of the late lamented President, have tended to settle in a practical manner some vexed questions in ethics. It is not going too far to assume in a general way that, in view of the experiences referred to, medical men have become more liberal on some points bearing upon their obligations to the public, and more absolute on others. While the position of the physician as an educated citizen is now more clearly understood than formerly, the lines are still more sharply drawn between the use of his privileges and the abuse of his professional prerogative. In other words, we are beginning to understand our proper attitude toward the public, and are preparing to act accordingly. Great crises, in which important medical questions are involved, create a demand on the part of the people for the expression of authoritative opinions. This fact has been strikingly manifested lately. The situation was forced upon the profession, and its responsibilities could not be ignored. Professional opinion concerning certain points in this remarkable case were eagerly solicited by the leading papers and were widely published over the country. While much was said that might better have remained unsaid, the testimony in the main was far from discreditable to scientific medicine. Notwithstanding the senseless adverse criticisms that obtained so much notoriety, and notwithstanding the widely advertised mistake in diagnosis, it is quite patent that surgery was able to explain in a very satisfactory manner the whys and wherefores of the results obtained. A more or less public discussion of the different professional aspects of the various questions involved was inevitable. What to say and what not to say became a question of wise discretion and good taste. Quite naturally there was room for a good deal of dodging around the border-line between self-advertisement and a dignified expression of accepted professional opinions.

The medical public, with a full understanding of its responsibilities, was in a proper position to make the distinction between speaking for the person in particular and for science in general. And now, when discussion is apparently at an end—at least in the secular press—it is comforting to think that the majority of those who published their opinions in the daily papers were so consistent as to the dignity of their calling, and so reserved regarding direct criticism of the management of another's patient. But the principle involved in this case has now a precedent for applicatio nin similar ones. Indeed, this ultimatum is tacitly accepted by the Committee on Ethics of the Medical Society of the County of New York, which, with becoming liberality, pointedly declares the proper relations between medical men and the public. It is clearly understood that it is not only the privilege, but the duty of a medical man to speak for his profession; to uphold its dignity to the public; to educate the people to the point of understanding why its science should be respected, and why its members should lead general opinion on all subjects pertaining to health and disease. On the other hand, it is declared with equal explicitness that nothing tends to lower the usefulness and influence of the profession more than the blatant twaddle of such as swallow their craft into their own personality, and use their opportunities only in the direction of individual advancement.

If medical men are prepared with such an understanding to act toward the public, we are convinced that nothing but good can result. There is no surer way, for instance, in checking quackery—professional and unprofessional—than in educating the public to the point of appreciating its absurdity. The better idea that the public can obtain regarding the science of medicine as a whole, the better will it be prepared to patronize educated medical men. The science of medicine may have a general application as regards the needs of the public at large, but the direct adaptation of its principles to the necessities of the sick individual must always be left solely with the properly qualified medical man. While no man can raise himself at the expense of the reputation of his craft, every individual is benefited when, by common consent, the honor and dignity of his brotherhood is consistently upheld. We can always do the latter properly, and at the same time rightly discharge our obligations to the public.

### GUITEAU'S DEFENCE.

THE points of interest in the trial of Guiteau since our last writing are the testimony of the prisoner and of the medical experts. The placing of such a prisoner on the witness stand in order to prove his

own insanity is a somewhat remarkable event in criminal history. The testimony which he gives is equally noteworthy. Guiteau displayed a wonderful acuteness in appreciating the legal bearing of the questions put to him, and in evading answers that would at all criminate him. He clung to his theory of Divine inspiration with a tenacity which might raise the suspicion that he appreciated its legal value.

Upon the general public the prisoner's quickness of mind and extreme adroitness probably made the most impression. Though mercilessly cross-examined, no inconsistency or incoherence was brought out. To the medical mind the fact that some confession of remorse and regret was made, as well as the undoubted mental suffering of the witness during the cross-examination, will perhaps have the most weight.

The expert testimony for the defence has just closed as we write. A number of medical gentlemen of high standing testified that if the statements made in the hypothetical question put by Mr. Scoville were true, the prisoner was insane. Several of the experts answered this hypothetical question under a kind of protest, in doing which they were quite justified. This question assumes, as established by the evidence, that Guiteau has a strong hereditary taint of insanity; that he was actually insane five years ago; that since then many persons had thought, from his conduct, that he was insane; that, last June, he became "demented with the idea that he was inspired by God" to kill the President; that after the act he became calm, as if he had performed a great duty; and that there was no other adequate motive for the deed than the conviction that he was executing the Divine will.

This question means simply: If he became insane five years ago, and was acting under an insane delusion when he shot the President, was he insane at the time when he committed the murder?

One may query, however, regarding the "strong hereditary taint," the insanity of five years ago, and the entire sufficiency of the inspiration as a motive. The prisoner's viciousness and vanity cannot be ignored in judging his motives.

The expert testimony for the defence seems on the whole to be rather unsatisfactory. The statement of one expert that he believed one out of every five persons was insane, quite destroyed the effect of his testimony, and did not help the popular repute in which medical experts are, often unjustly, held.

It may be remarked that the criticisms in the daily papers have, as a rule, shown a great incapacity to grasp the questions involved. What the jury should know is, first, whether Guiteau's act was the offspring of a diseased brain, or of a vicious nature, or whether it came from a mingling of both; and, second, whether in any case he should be punished.

### HYDRANGEA IN RENAL CALCULI.

THE article by Dr. Edson, seemingly confirmatory of the good effects of hydrangea in renal calculus, deserves some attention by practitioners who are looking about for the means of preventing attacks of renal calculi. Two years ago Dr. E. B. Freeman, of Barton, Ala., described in glowing terms (*vide* MEDICAL RECORD, vol. xvii., p. 471) the virtues of hydrangea as a solvent in renal calculi. For a long time a sufferer from the latter affection, he was finally completely relieved by this drug. A second case in which the same remedy was employed proved equally successful. Dr. Edson now adds his experience in the same direction, and in a manner calculated to draw renewed attention to the subject. Although it must be admitted that the statements of these gentlemen may appear a trifling too positive, it is well to remember that the drug has not been hitherto without a reputation as a remedy in this apparently intractable affection. It was first employed for the purpose named, and with good results, forty or fifty years ago, by Dr. E. Butler, while a missionary among the Cherokee Indians, and it has since been recommended by different physicians at various times, among others by Drs. W. L. Atlee, Horsley, and John C. S. Monleur. It would now appear probable that a more extended trial of its supposed virtue is to be made.

---

### REGULATING THE PRACTICE OF MEDICINE.

QUITE recently we took occasion to refer to the inadequacy of the present law for regulating the practice of medicine in this State. At the recent meeting of the Medical Society of the County of New York the subject was quite pointedly discussed in the addresses of the retiring and incoming presidents of that body. As will be seen by a reference to our report, published in the present issue, the difficulties in the way of the enforcement of the law are many and significant. As has been truly said, there has been from time immemorial a tendency for quackery, even in its most pronounced forms, to flourish, despite apparently stringent enactments to the contrary. While we should not despair in our efforts to reform the present condition of public opinion, it is quite evident that many difficulties are yet to be encountered before desirable results can be realized. We are, for instance, met with the apparent impossibility of reconciling the principle of liberty of the subject by any enactment which can be construed as having a contrary tendency. In reference to any law aiming to create qualified practitioners, the special plea on behalf of legislators is to the effect that thereby the right to choose his own physician by any citizen is directly interfered with. Then again comes the present hinderance in the way of fixing upon any universal and satisfactory standard of qualification for medi-

cal practitioners. When to these militating influences are added the interested opposition of all varieties of quacks who would be injured by such a law, and the well-known apathy of the grand jury, as shown by its action in cases recently before it, and, finally, by the want of interest in the subject manifested by the public at large, and even by members of the profession, the prospects are not very promising. Still it is well to appreciate the obstacles to be encountered, and to overcome them in an intelligent, liberal, and determined manner. That no law has yet been enacted to suppress quackery is no reason why we should be discouraged, but rather proves what yet remains to be done before the triumph over quackery can be complete. One of the principal means to the desired end is the proper education of the public upon the subject. This process is a gradual one, it is true, but the surest in the end. It is gratifying to learn that the County Society is not yet disheartened, and that there is still a laudable determination on its part to continue the good fight against charlatanism in all its various forms. There is every reason to believe that the work is properly begun, and that the reformers are making substantial progress.

## Reviews and Notices of Books.

ARTIFICIAL ANÆSTHESIA AND ANÆSTHETICS. By HENRY M. LYMAN, A.M., M.D. New York: William Wood & Co., 1881. Wood's Library of Standard Medical Authors.

A PERUSAL of Prof. Lyman's work leaves us considerably impressed with the industry and knowledge of the author, as well as with the usefulness of his treatise. He has discussed his subject very thoroughly, and has touched upon every point connected therewith. The history, phenomena, and physiology of anæsthesia are first given; then follows a description of the methods of producing anæsthesia, with the various instruments used for the same. Accidents of anæsthesia and their treatment, anæsthesia in obstetrics, and in dentistry, the mortality of anæsthesia, and the medico-legal relations of the same are also taken up. A description is given of forty-eight different anæsthetics, or anæsthetic methods, a list which includes everything, we believe, except the mesmeric sleep.

The author writes in a clear, elegant, and forcible style. His physiological explanations are especially good, and everywhere an excellent judgment is shown in commenting upon debated points as to the use or action of anæsthetics. The book is, of course, very largely a compilation, but the work is excellently done, and it makes, perhaps, the best, most complete, and practical treatise on anæsthetics that we have.

MANUAL FOR THE PHYSIOLOGICAL LABORATORY. By VINCENT HARRIS, M.D. (Lond.), and D'ARCY POWER, B.A. (Oxon.). New York: William Wood & Co.

THIS work is essentially an epitome of histology and of physiological chemistry. It contains also brief directions for the preparation of tissues for microscopic examination. The facts are given in a very concise and clear manner. Altogether, the book ought to prove a very helpful one to the student.

A TREATISE ON COMPARATIVE EMBRYOLOGY. By FRANCIS M. BALFOUR, LL.D., F.R.S. In two volumes. Vol. ii. London: Macmillan & Co. 1881. 8vo, pp. 655.

THE present book completes Dr. Balfour's treatise on comparative embryology. Like the preceding volume, it represents an immense amount of patient research, as well as a wide range of scientific and bibliographical knowledge. It would be impossible to make any critical review of its contents. The embryology of the vertebrates is treated of in this concluding volume, and it contains chapters, therefore, which come more nearly within the knowledge of medical readers. The first part treats of the developmental history of the chordata. Three chapters are then devoted to a comparison of the formation of the germinal layers and of the early stages in the development of vertebrates. The remainder of the work is devoted to a history of the development of the different organs of the body. Considerable space is given to human embryology. The work is beautifully and copiously illustrated. There is also a very complete bibliography. We cannot praise too highly the efforts of the author, which have resulted in making so exhaustive and valuable a contribution to natural science. It easily takes the first rank among treatises upon embryology in any language.

DIE AMPUTATION DER GLIEDMASSEN DURCH ZIRKELSCHNITT MIT VORDEREM HAUTLAPPEN. Von VICTOR v. BRUNS. Tübingen: Verlagder H. Laupp'schen Buchhandlung. (Amputation of Limbs by the Method of Circular Incision with Anterior Flap. By VICTOR v. BRUNS. Tübingen: H. Laupp's Publishing House. 1880.)

RECOGNIZING the importance of a thorough knowledge of the various steps by the observance and execution of which success is secured in amputations by the method of the circular incision with an anterior flap, Dr. v. Bruns has written a treatise upon the *modus operandi* adapted to the wants of the practical physician. A very extended experience in amputations allows him to speak with some authority.

The method of circular incision with anterior flap was introduced by the author in 1844. The following advantages over methods by uni- or bi-lateral incisions are claimed for it: it allows of a more rapid healing; healing takes place with the formation of a better stump, inasmuch as the end of the bone is not covered by cicatricial tissues, but by normal skin, and the cicatrix is situated at a distance from the osseous extremity at the periphery of the stump on its posterior aspect.

The book contains the following chapters: An Historical Introduction; General Considerations of the Various Steps in Amputation by the Method of the Circular Incision with an Anterior Flap; Instrumental and Bandaging Apparatus, Technical Execution of the Operation of Amputation by the Method of Circular Incision with Anterior Flap; Treatment Subsequent to Amputation; Concluding Remarks.

The language is clear and concise. We take pleasure in recommending the book to the profession.

STUDIEN ÜBER KÜNSTLICHE GLIEDER. Im auftrage des Königlich Preussischen Kriegs-Ministeriums bearbeitet von DR. O. KARPINSKI, Oberstalsartzt, etc. Hierzu ein Atlas. [Berlin: E. S. Mittler und Sohn. 1881. (Studies in Regard to Artificial Limbs. By DR. O. KARPINSKI, Chief Staff Physician, etc., in Accordance with an Order of the Royal Prussian Ministry of War. With an Atlas.)

IN 1878 Dr. Karpinski was commissioned by the Prussian Ministry of War to report his experience and observations in regard to artificial limbs, their modifications as necessitated by the shape of the stump, the merits and demerits of artificial members manufactured by the various firms, etc. He has made an exceedingly thorough and careful study of the subject in hand, and has contributed a work of very great practical interest to the medical profession and the mechanician. A beautifully executed atlas, containing illustrations of the different kinds of artificial limbs used from the fifteenth century down to the present day, accompanies the text.

In regard to the construction of artificial limbs in America, the author says that, although shortly after the war of the Rebellion, we excelled all other nations in this respect, and further, that, though our productions were numbered among the best at the Paris Exposition of 1869, it is questionable whether we surpass our European competitors at the present time.

# Reports of Societies.

## NEW YORK PATHOLOGICAL SOCIETY.

*Stated Meeting, November* 9, 1881.

DR. GEORGE F. SHRADY, PRESIDENT PRO TEM.

### CHRONIC INFLAMMATION OF THE BLADDER ASSOCIATED WITH CYSTIC DEGENERATION OF THE KIDNEYS.

DR. B. A. WATSON presented a specimen with the following history: J. H. W——, born in Massachusetts, forty-seven years of age, and a cracker-pedler, was first attacked with cystitis about thirteen years ago, and had since suffered periodically with fits of gravel, while his urine had been constantly ammoniacal, loaded with pus and a substance which the deceased designated as "white sand." Six or seven years ago the urethra was completely obstructed by a stone, which was so large that it could only be removed in fragments, and since that time he had always been compelled to void his urine at least once every hour. Last May this patient came under the professional care of Dr. F., who referred him to Dr. T. The latter examined for stone in the bladder, with a negative result, but the introduction of the sound was followed by a protracted hemorrhage, and in connection with it there was a profuse discharge of that which has been previously mentioned as "white sand." The diagnosis made at that time was "chronic cystitis with hypertrophy of the walls of the bladder." Cystotomy was recommended, but not performed, and the patient was treated with atropia and dog-grass. No additional information from that date until the 6th of last October was obtained, when the patient, who was suffering from retention of urine, again applied to Dr. F., who requested Dr. H. to pass an English No. 8 catheter. The following day the latter made a careful examination of the patient's urethra and bladder, and found in the bulbous portion of the former a slight stricture, which he dilated in two sittings so as to be able to pass an English No. 13 sound; and he also discovered that the latter organ was greatly contracted. Twenty-four hours after that examination a hemorrhage began, which lasted thirty-six hours. The cessation of this bleeding was followed by a slight, though brief improvement in the symptoms, but during the night of October 11th he was slightly delirious, and on the following day the attending physician diagnosed diphtheria. The patient, probably somewhat influenced by the grave character of the prognosis, and apparently unwilling to await the slow progress of disease, sought a favorable opportunity, and terminated his existence by sending a pistol-ball through his brain on October 12th.

*Post-mortem appearances.*—The physician making the autopsy failed to note the external appearances of the body beyond the pistol-wound in the temple, which, he says, caused death. In fact, the report was entirely limited to the pathological specimen presented to the society, and Dr. Watson, therefore, concluded that there was nothing else observed worthy of study. The fact was mentioned that the right kidney was larger than the left—the former weighed, before it was opened and the fluids thus permitted to escape, fifteen ounces, while the latter weighed only eleven—and that the cysts in both contained "a milky fluid," which, as was added, resembled "a broken-down cheesy deposit."

*Remarks.*—"It will undoubtedly be admitted that the bladder in this specimen furnishes a good representation of the local effects of chronic cystitis. The mucous membrane, prior to its being placed in alcohol, possessed the characteristic brown color, and the marked hypertrophy of the walls of this organ may still be examined. The right ureter is much more capacious than the left, and in this respect corresponds with the kidneys, where the chief interest of the specimen probably centres. The cystic degeneration has already been mentioned, but it will be observed that there is also in these organs an abnormal quantity and distribution of fat. Is this fatty condition a part of the cystic degeneration, or have we in these organs both fatty and cystic diseases? The etiology of the kidney disease and its relation to the chronic cystitis may also be worthy of some consideration in connection with this specimen. The history of the case renders it quite certain that cystitis was the primary lesion."

### NECROSIS OF THE CLAVICLE RESULTING FROM INJURY—SUB-PERIOSTEAL REMOVAL OF A PORTION OF THE BONE IN ITS ENTIRE LENGTH—RECOVERY, WITH A USEFUL ARM AND A REPRODUCTION OF THE WHOLE CLAVICLE.

DR. JOHN A. WYETH presented a patient with portions of necrosed bone, with the following history: Edward M. Conley, sixteen years of age; no family history. February 21, 1881, had his left clavicle dislocated at the sternal end, and broken at the junction of the outer and middle third, by a lad who caught him by both shoulders from behind and violently pulled his shoulders backward. Two days later a surgeon attempted to reduce the dislocation, and a "Sayre dressing" for fractured clavicle was applied. On February 28th, seven days after the accident and five after he was thus treated, he came under Dr. Wyeth's observation. After the dressing had been removed, he found a tumor as large as a lemon at the sterno-clavicular articulation, which he

immediately opened; it discharged about two ounces of pus. Within the next few weeks two or three other sinuses opened in the course of the clavicle, giving evidence of extensive necrosis. On May 7th he removed all of the diseased bone. The incision extended from the *sternum* along the bone to the acromion process. The periosteum was laid back to either side of the incision, and about twenty pieces (the largest about two inches in length) were removed. Three-fourths of an inch of the sternal end was removed entire. When the bone showed evidence of life, that is, when it looked red and sound, he chiselled off the necrosed tissue to this line of living bone, and it was left. Upon this osseous and periosteal nucleus a new and useful clavicle had been produced. On July 7th the lad was put at work as a telegraph messenger.

DR. BRIDDON asked if the health of the patient, previous to the accident, was good. He thought that it was an unusual result to follow an injury of that character.

DR. WYETH replied that, so far as he had been able to ascertain, the previous health of the patient was good, although he had not been an extremely rugged boy.

DR. RIPLEY remarked that the injury itself was unusual, and he thought there was some vice in the system to explain its gravity.

DR. BRIDDON said that twenty years ago he reported a case in which acute necrosis took place with diaphysis of the clavicle. The entire clavicle was removed, but it was reproduced entirely, and the result was so perfect that the injured could not be distinguished from the sound bone.

DR. GERSTER asked if there was any external wound at the time of the injury.

DR. WYETH replied that the injury was subcutaneous throughout.

DR. GERSTER remarked that the results were admirable, and he then drew attention to one point, which seemed to be of some interest, namely, the pathology of these cases. He had seen only two cases in which the cause was similar to that operating in Dr. Wyeth's case. Some younger person sustains a fracture of the clavicle entirely subcutaneous, and suppuration takes place about the fractured point. He inquired whether any of the members had seen such cases. Dr. Wyeth's was the third which he had seen, and he could not explain why subcutaneous fracture should go on to suppuration.

DR. WYETH suggested an explanation, namely, that there was displacement of the bone, removing it considerably from its original position and necessarily severing all arterial communication. Probably the nutrient artery was severed at the time the fracture was produced, and those facts perhaps might account for the general necrosis which occurred.

DR. BRIDDON doubted whether the suggestion made by Dr. Wyeth concerning division of the nutrient artery of the bone would account for the condition which followed, because fractures at that point were met with over and over again, and yet necrosis did not occur. He thought there was some constitutional vice in this case which explained its subsequent history.

DR. WYETH admitted the influence of a constitutional vice, but he thought it possible that the necrosis might in part be explained by the disturbance in the circulation. He remarked that bones were exceedingly vital, as proved by experiments made by Macewen, of Glasgow, who removed in one case nine inches of the humerus in a child, and took chips of bones half an inch in length or more from an amputated limb and placed them in the opening, and they united and new bone was produced throughout. That would seem to prove that bone possessed a greater vitality than it had heretofore been credited with. Certainly, simply slipping the bone and dividing the nutrient artery would not explain the necrosis without some constitutional condition.

DR. BRIDDON remarked that Dr. Macewen's experiments also proved that the nutrient artery was not essential to the life of bone.

DR. PUTNAM-JACOBI thought that the nutrient artery was of little importance in sustaining the life of the bone, as compared with the blood-vessels which come from the periosteum.

DR. WYETH remarked that both sets of vessels had been considered as essential to the life of bone. He also referred to experiments performed by a German surgeon, who cut out chips of bone without reference to shape, and placed them in openings in other bones without reference to the position of the periosteum, and serviceable bones were the result.

### RUPTURE OF THE JEJUNUM.

DR. W. M. CARPENTER presented a specimen which was interesting, especially with reference to one or two points in its clinical history. It was removed from the body of a man forty years of age, a hod-carrier, who fell from the third story of a building. He was removed in an ambulance to Bellevue Hospital, and the following items in the clinical history of the case had been furnished by the house surgeon, Dr. Hartley. On examination there was found double Colles' fracture; also an incised wound extending downward from near the angle of the mouth on the right side, over the lower jaw, to the extent of two inches. There was evidence of contusion over the right ilium and over the lower portion of the right side of the thorax. On admission, the patient complained of pain, which he referred to the right side of the abdomen and the lumbar region. He was in a condition of shock, although it was not profound. There was pallor, but not marked; there was coolness of the surface of the body and extremities. His pulse was 120 and feeble, and he had vomited once. He was also restless, and his countenance was somewhat anxious. Fomentations were applied over the abdomen, and a hypodermic injection of morphine was administered. The symptoms of shock all disappeared, so that a few hours after admission the patient's pulse was 90 and full; his skin was warm and moist, and his general condition was very good. The only thing of which he complained was the pain referred to the right side of the abdomen. About twenty minutes before his death he was seen by the house surgeon, and this condition of general comfort still existed. The orderly suddenly noticed that there was a change in the general appearance of the patient, went to the bedside, found that his extremities and the surface of his body was cold; immediately called the house surgeon, who quickly arrived, but found that the patient was dead. At no time were there any head symptoms.

At the autopsy there was found double Colles' fracture and the incised wound already described. There was evidence of contusion over the lower portion of the right side of the chest and over the right ilium. On opening the abdomen gas escaped freely, and the cavity contained several ounces of bloody

serum, with some fecal matter. The liver, the spleen, and the kidneys were apparently normal. The lumbar muscles were contused, and contained extravasations of blood. In the jejunum there was found a rupture, which extended about half-way around the gut. Plastic exudation was found upon the convex surface of this portion of the intestine, extending along its convex surface to a distance of fifteen or eighteen inches. The thoracic organs were normal. The brain was not examined. The chief points of interest in the clinical history of the case were the difficulty in diagnosis and the almost complete restoration from the shock. The house staff were unable to reach a positive diagnosis as to whether there had occurred laceration of the liver, laceration of the spleen, or whether there was internal hemorrhage, or whether there had been rupture of the intestine. The patient died eight hours after admission.

Dr. Briddon remarked that the specimen possessed special interest in connection with the subject [peritoneal surgery] which had recently been under discussion, and illustrated the difficulty in making a positive diagnosis in cases of abdominal injury. In the present case there was nothing by which a positive diagnosis could be made, and certainly there was nothing sufficiently positive to warrant any surgical interference with the abdominal cavity.

Dr. Putnam-Jacobi suggested that the restoration from shock could be explained on the supposition that there was only partial rupture of the intestine at the time of the accident, and that at the time of or just before death the rupture became complete, and gave rise to the secondary shock.

Dr. Geo. F. Shrady suggested that there might have been complete rupture with moderate escape of intestinal contents, then a temporary arrest of the escape followed by temporary reaction, and finally another escape of intestinal contents, which was the immediate cause of the shock and death.

Dr. Wyeth referred to two cases, met with by Dr. Janeway, in which sudden death was produced by fracture of the odontoid process, and suggested the possibility that in the present case the sudden death might have been caused by such an accident which had passed unrecognized.

### SUDDEN DEATH WITHOUT ASSIGNABLE CAUSE.

Dr. Van Gieson presented a brain with the following history: "The patient from whom this specimen was taken was first seen by me in June, 1878. He was at that time a well-nourished man of about forty-six years of age, the eldest of three children of healthy parents, well advanced in life, and free from hereditary taint of any kind.

"In the summer of 1875, three years before I saw him, he suffered from what was called a heat-stroke. He was suddenly seized, on a very warm day, with giddiness, headache, and strabismus. After about a week he recovered from this and resumed his business, that of a clerk. Close application to work brought on severe headaches for a long time afterward. The strabismus disappeared a day or two after the attack of heat-stroke.

"From that time until the early part of 1878 he was comparatively well; but he was then seized with intense supra-orbital headache, very severe and prolonged; he nevertheless kept at his desk until February 22d, when he noticed that he was unable to open his right eye, and that the eye itself was very much turned from its axis toward the right; not long afterward the left eye gradually became similarly affected. In June of 1878 the left eyelid was almost entirely paralyzed. During this latter period his memory for recent events was much impaired, but the intellect and judgment were clear. The appetite was good and the bowels regular. At times the pain seemed periodical, but the element of periodicity was not noticeable during the latter part of the disease.

"I first saw the patient on June 13th, in consultation with Dr. E. G. Janeway and Dr. O'Brien. He was then free from pain; answered questions readily and intelligently; the muscular grasp was of fair force and equal; movements of limbs co-ordinate; no evidence of paralysis, except in the parts already described. Ophthalmoscopic examination revealed no lesions of fundus; both eyelids show nearly complete ptosis, most marked in the right; both globes strongly diverged.

"Searching questions reveal probable syphilis, apparently arrested by treatment some eighteen or twenty years ago. No nodes or thickening of scalp can be discovered. The disease is diagnosed as third paralysis, from the remote effects of venereal disorder. The lungs and heart were carefully examined, with negative results. Repeated examinations of the thoracic organs, made during the further progress of his disease, revealed no appreciable lesion. Frequent examinations of the urine showed no trace of anything but slight deposits of urates from occasional overloading of the stomach and consequent temporary gastric derangement.

"It was agreed to treat him with large doses of iodide of potassium, increasing daily until the point of intolerance was reached. The initial dose was two scruples, in divided doses, daily.

"On July 29th the daily dose was six and one-half drachms; he continued with this until August 10th. There is as yet no visible improvement. The patient has diarrhœa, sore throat, reddened fauces, and burning pains in the stomach.

"The dose was now reduced to three drachms daily.

"August 15th.—The foregoing symptoms still persisting, the iodide was withdrawn entirely and tonic doses of strychnine, quinine, and iron, given.

"September 5th.—General health improved; local condition about the same; appetite and sleep good.

"September 15th.—Resumed the kali iod., alternating with $\frac{1}{24}$-grain doses of hydrarg. bichloride.

"December 2d.—Withdrew the bichloride, and gave ½ to ⅔ of the proto iodide in its stead.

"April 1, 1880.—The patient has been seen at intervals, and the mercurials and iodides kept up; the ptosis of the left eye is disappearing as well as the divergence; the right eye is better, but in a less degree.

"February, 1881.—Has been seen at intervals of four to six weeks. There is gradual improvement in the right eye—the pupil can be brought nearly to the normal centre of vision; treatment suspended for a few days, and tonics given in the interval.

"March, 1881.—Ptosis of right eye, not marked except when patient is much fatigued. Right eye can be brought fully up to the normal axis *when the left eye is closed*, but when both eyes are open, the right still diverges a little.

"April 5, 1881.—Called suddenly to find the patient suffering from severe pains in right shoulder and elbow. There is no redness or swelling; the pulse and temperature are normal. The tongue shows superficial erosion and slight indentation.

"April 8, 1881.—The arm from the shoulder to elbow is intensely ecchymosed, much resembling the appearance of the parts some hours after a fracture of the humerus; there is slight swelling; the pain has disappeared. This condition of things is diagnosed as being caused by self-inflicted violence during a night-convulsion.

"May 20, 1881.—The right arm shows the same condition of things in a less degree; the tongue shows no marks of having been bitten.

"June, 1881.—Slight lingual paralysis—unable to talk for several minutes; eyeballs protruding and staring expression of the face; difficulty in swallowing; partial loss of consciousness; the whole attack estimated roughly as lasting some ten minutes. He had entirely recovered when I saw him about a half-hour from the beginning of the attack, and could give no intelligible account of it.

"September 11, 1881.—3 A.M.; a similar attack, lasting but a few minutes; the tongue is bitten on one side.

"September 24th.—Another and severer attack, accompanied with slight convulsive movements.

"October 16th.—A violent, long-continued convulsion, beginning at 9 P.M.; at the beginning the eyes were fixed for an instant, then the hands and feet were drawn rapidly backward and forward, and the muscles of the trunk were in a state of tonic spasm; attending the movements were loud shrieks and groans; there was no frothing at the mouth, and but slight mucous râles in breathing; as the movements of the limbs subside, the head was rolled rapidly from side to side, and after a time came an interval of rest, but no return of consciousness. Then followed another severe convulsion up to 9 A.M. of the 17th; twelve hours after the first attack he had nine convulsions.

"On the 18th he was again quite well, suffering only from lameness in the shoulders and arms.

"October 21st.—Is very much prostrated, and prefers to lie in bed.

"October 27th.—Is again about, apparently as well as usual. The bowels have not been moved for a week. One-half minim of croton-oil produced a free movement, after which he declared that he felt better than he had for months, and desired to go out. It was not deemed safe to grant him permission so to do.

"November 8th.—Awakened feeling unusually cheerful. On coming out of the bath-room, where he had been washing, he passed through the hall and entered the adjoining room. His sister, sitting near the window—he just within the door—noticed that he stood rigid, with fixed eyes, as if dazed by the light. She hastened to him, fearing that he was about to have a convulsion; but, before she reached him, he fell sidewise to the floor, breathed stertorously for a few minutes, and died.

"I made the necroscopy with the assistance of Mr. E. Wilson, my student, at 11.30 A.M. to-day, some twenty-seven hours after death. Only the head was examined. After removing the calvarium, its inner surface was examined and found free from exostosis; the cerebral surface was but moderately congested; the vessels of the pia mater contained rather less than the usual amount of blood; there was no effusion of blood, either on the surface within the ventricles, or in the substance of the brain.

"On the inferior surface of the brain the most noticeable feature was the large size of the basilar artery, its diameter being probably one-fifth larger than the average, though the brain itself was a large one, weighing fifty-six and three-fourths ounces.

"The artery was also the seat of extensive atheromatous degeneration. The minuter arteries have not been carefully examined; it is probable that they are in some degree similarly affected. The protruding ends of the internal carotids are also the seat of atheromatous changes. At the posterior border of the choroid plexus, just where it dips down into the posterior horn of the right lateral ventricle, there are two small, lens-shaped growths of firm texture, buff-colored, and of about the size respectively of a small split-pea and kidney-bean. These are the only lesions apparent upon the superficial examination thus far made, and they seem hardly sufficient to account for the sudden death.

"The diseased condition of the arteries has no doubt existed for a long time, and was looked for with some degree of confidence of finding associated with it somewhere a rupture of the arterial walls. Thus far no such condition has been found, and further, the basilar artery is not occluded, but freely pervious in all its course. The same is true of all the arterial trunks and branches visible on the inferior surface of the brain. In the absence of any gross lesion, and after a reconsideration of all the symptoms, we are met with the question, so often propounded after the most searching post-mortem examinations, What, after all, was the immediate cause of death?"

DR. WYETH had seen a case with Dr. Weber, in which the clinical history was almost identical with that given by Dr. Van Gieson. In that case the basilar artery was occluded. He also referred to eight cases reported by Dr. Hammond, in which there was occlusion of the basilar artery, and the mode of death was like that which took place in Dr. Van Gieson's case.

DR. SHRADY suggested that in Dr. Van Gieson's case the basilar artery was not entirely occluded.

DR. CARPENTER suggested the possible existence of fatty degeneration of the heart as an explanation of the sudden death in Dr. Van Gieson's case. He then referred to a case recently reported by Dr. Noeggerath, in which the heart was carefully examined with a view to the administration of anæsthetics for the performance of an important surgical operation. It was decided that the heart was perfectly healthy, and there was nothing in the history of the case to indicate that there was any cardiac disease. The patient died suddenly a few hours after the operation. At post-mortem there was found extensive fatty degeneration and infiltration of the heart-muscle, and the sudden death was attributed to paralysis supervening upon that pathological condition. The patient rallied from the operation, and there was no internal hemorrhage.

DR. VAN GIESON said that such cases were more or less capable of diagnosis, as there was usually great fatigue upon exercise, shortness of breath, and other rational symptoms.

DR. PUTNAM-JACOBI referred to the occurrence of symptoms of pseudo-apoplexy depending entirely upon the weakened condition of the heart and circulation, and in which patients lost consciousness over and over again, and then passed on apparently as healthy as before. Dr. Stokes had directed attention to a number of such cases, in which the valves of the heart were perfectly free from lesion, and the only physical signs that could be obtained of cardiac disease was weakened impulse, weakened first sound, and very slow or exceedingly rapid

pulse. In those cases sudden death frequently occurred.

Dr. Van Gieson remarked that he had frequently seen such cases, but had never seen convulsions in such a case.

Dr. Ripley referred to the fact that in quite a proportion of cases patients suffering during life from marked brain-symptoms which led to the supposition that at the autopsy important pathological changes would be found, but in which substantially nothing was revealed. He referred to a case which came under his observation eight years ago. The patient had suffered from sunstroke, and from that time onward he had severe headache. His mind gradually failed, and about six weeks before his death he became semi-comatose and died in that condition. At the autopsy, which was made by Dr. Delafield, nothing was found which explained the cause of death. Dr. Delafield also made a microscopical examination of the brain, and then was unable to find the cause of death.

Dr. Putnam-Jacobi remarked that the brain-lesions were usually only the approximate cause of death. Persons with tumors in various parts of the brain often died suddenly, and under such circumstances, although the tumor had existed for a long time, it could be regarded only as the remote cause of death, for death was produced only by inhibiting the cardiac centre or the respiratory centre of the medulla. If the basilar artery was diseased, as it was in Dr. Van Gieson's case, its branches would also be found in a more or less diseased condition. Those which passed into the pons might be so diseased as to obstruct the circulation, and thus the convulsions would be explained. Those which passed to the respiratory centre in the medulla might be so diseased as to temporarily plug the arteries, and thus give rise to sudden death. She was not able to understand why it was necessary to have a larger lesion than that apparent in Dr. Van Gieson's case to explain the sudden death. Of course, in this estimate the existence of cerebral hemorrhage or lesions of that character were to be excluded.

Dr. Van Gieson thought that in cases in which, from the character of the symptoms during life, it was expected that marked gross lesions would be found at the autopsy, we were frequently disappointed.

Dr. Ripley remarked that sudden death from cerebral hemorrhage was exceedingly rare. In almost all of those cases in which sudden death was supposed to be due to cerebral hemorrhage, the immediate cause was due to some other lesion. He had not seen a case in which sudden death had been produced by cerebral hemorrhage.

Dr. Carpenter remarked that he had seen a number of cases in which it was evident that sudden death had been produced by cerebral hemorrhage, as proven by the autopsy.

(To be continued.)

A Successful Gastrotomy has been performed recently by Mr. Jones, of the Manchester Royal Infirmary, England. The patient, a girl, aged twenty-one, had stricture of the œsophagus, caused by swallowing nitric acid two years before. Bougies had been used at intervals, but finally none could be passed. The operation was performed in two stages, according to Mr. Howse's plan. Everything worked successfully, and the patient, since the establishment of the fistula, has gained twenty pounds.

## MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

*Adjourned Annual Meeting, November* 28, 1881.

Dr. A. E. M. Purdy, President, in the Chair.

After reading the minutes of the annual meeting held October 24, 1881, the Secretary read the

REPORT OF THE COMMITTEE ON ETHICS,

submitted by its chairman, Dr. E. Darwin Hudson, Jr. The committee reaffirmed the view presented by the Committee on Ethics last year, namely, that "it is undignified and unprofessional for a member of the profession to lend his name and indorsement to an advertised or patented medicine."

The committee had found no occasion for recommending discipline. While regarding the willingness of physicians to appear often in print as in very bad taste, the committee did not object to occasional communications or interviews on subjects of absorbing public interest.

The committee could not endorse, in its present form, the resolution concerning interviewing, introduced by Dr. C. D. Varley at the stated meeting held September 26, 1881. The resolution was: "*Resolved*, that the profession, so far as represented by this body, entirely disapprove of the recent system of interviewing, considering it contrary to the dignity and etiquette of the medical profession, especially when held in reference to the condition and treatment of patients not under our care, and concerning whom we have no knowledge except from hearsay report."

The interviews alluded to, the report went on to say, "were based upon reports and knowledge promulgated in official daily bulletins and personal experiences to the press by the attending physicians. Hence, they constituted a proper basis for just comment." The committee reported, however, that they deprecated the departure from the spirit of the code of ethics in the reported conversations or interviews with reporters of several prominent physicians, in which they criticised or attacked the character and conduct of the physicians attending a case of which they had no personal knowledge.

The report was accepted and ordered upon the minutes.

The retiring President, Dr. A. E. M. Purdy, then briefly reviewed the work done by the society during his administration, especially in the direction of efforts to enforce the medical law passed in May, 1880.

The address began with a quotation from the remarks made by Mr. Rivington (Carmichael Prize Essay): "Unqualified practice has prevailed from time immemorial, and appears likely to prevail in all time to come. The grievous harm done by common artificers and ignorant pretenders has been the subject of comment and assigned as the reason for legislation, but the result has always been the same: quacks have continued to abound and flourish, and unqualified persons have continued to practise and prescribe. It cannot be otherwise so long as the Legislature proceeds upon the principle—the liberty of the subject. It is held that any man has a right to choose his own doctor—qualified or unqualified." In this country and in this State the question of the suppression of "empiricism" was agitated in 1796 and 1805, and in 1806 the first "Act to regulate the practice of physic and surgery" was passed. In 1818 this society urged the profession in general to comply with the

law. In 1819, suits were begun against unlicensed practitioners. In 1822, it was proposed to publish a list of "legal practitioners," but objection was made because it was difficult to decide who belonged to that class. In 1823, a committee was appointed "to devise a system of association calculated to advance the interest and honor of each individual member," and they reported that the object of all associations was "interest and improvement," but "at times neither is obtained because members are sometimes too selfish and sometimes too indolent, and the contempt of the public is the consequence." The President queried whether all the members at the present time had manifested a commendable degree of zeal in the work which the society had been struggling of late to perform, especially those who had manifested a disposition not to pay their assessments.

In 1824, a census of physicians was made, and in the same year the society passed a resolution condemning the giving of certificates to quack or secret remedies. In 1830, Dr. Piexotti, President of this Society, memorialized the Legislature concerning the great prevalence of quackery, and the necessity for enactments to exclude from the practice of the healing art all ignorant pretenders and knavish impostors. In 1831, this society pledged itself "toward the suppression of quackery in every form," and so the struggle went on until 1866, when the Metropolitan Board of Health was established, and every physician was required by law to register his name in a book in charge of that Board. The desired force of the requirement, however, was lost, because the Registrar did not know what constituted proper credentials, and at the same time was unable to refuse registration. Under the law of 1874, the board of censors made a careful census of the practitioners in the county, and for a time, at least, succeeded in driving from the city nearly four hundred irregulars. The President then quoted quite extensively from an article on "The Statutes Regulating the Practice of Medicine," written by Dr. Ernest W. Cushing, and published in a late number of *The International Review:*

"In the first place, it cannot be denied that any law restricting the right of all persons to practise medicine secondarily interferes with the right of every one to choose his own physician, and is thus doubly an invasion of perfect freedom.

"The second obstacle to regulation of medical practice by statute is the difficulty of fixing the proper standard of professional attainment, owing to the great difference in the requirements of various medical colleges.

"The third obstacle to medical legislation is the opposition of the spiritualists, clairvoyants, magnetic rubbers, and charlatans of every kind."

"Perhaps the greatest obstacle to such a law is the feeling on the part of the public that any such legislation would greatly, if not unduly, favor and protect the medical profession against the competition from quacks."

The President also alluded to other obstacles: the two principal systems on which medical statutes had been framed—the Continental and the English, and came to the laws passed in New York and other States. Some account was given of the obstacles to the enforcement of the law of 1880, and the manner in which the apathy and lack of sympathy of the Grand Jury was manifested. For example, such questions as the following were put to him by members of the Grand Jury: "Is it necessary for a man to have a diploma to practise medicine?" "Has he killed anybody?" "Has this prosecution anything to do with the schools?" "What interest have you in this matter?" Reference was then made to special cases in which only a partial success had been obtained. For example, Dr. ———, the notorious catarrh doctor, was indicted for misdemeanor instead of for perjury, fined one hundred dollars, and escaped.

Gratifying indeed would it be could we bear testimony to the total extinction of quackery, but great must be the change in public opinion before we can arrive at so happy a result. The interests and character of the profession and the public good required combined and patient effort toward securing such legislative enactments as might be necessary to protect medical science.

During his official connection with the society—ten years as secretary and three years as its presiding officer—its numbers had increased from two hundred and fifty to above eight hundred, and surely such a growth must be gratifying to all who had been associated in its management. Of those with whom he had been associated in an official capacity, many had passed away, some weighted with years and honors, others just as their day of usefulness was dawning. Their memories are hallowed, and their examples are a precious heritage. Bibbins, Underhill, Elliot, Peaslee, and a score of brilliant, earnest workers are gone. But, taking fresh courage, may we labor on, holding high the standard, united in a common cause, the universal brotherhood of our profession, the elevation of the science and the art of our calling, and the amelioration of the sufferings of the race.

With gratitude for the uniform courtesy and kindness of his brother officers and fellow-members, he commended to the society his successor in office, and asked for him a hearty support and earnest co-operation.

Dr. O'Sullivan referred to the good and useful work done by the society in its efforts to suppress quackery, and believed that much of the success obtained had been due to the unceasing labor and untiring energy of the retiring president.

On motion made by Dr. O'Sullivan, the society unanimously extended to Dr. Purdy its hearty thanks for the uninterrupted service which he had given to it during the last thirteen years.

The society then adjourned.

---

### Stated Meeting.

The stated meeting held on the same evening, was called to order by the President, Dr. F. R. Sturgis.

#### The President's Inaugural Address.

The policy of the coming administration was sketched, and special attention directed to some of the deficiencies of the medical law of 1880, under which the prosecutions of the past year have been made.

In the first place, the law does not include many who ought to be regarded as legal practitioners of medicine. For example, one Dr. Kraft escaped indictment because he swore that he cured diseases by electricity, and did not prescribe medicines. The Justice held that Kraft was not a physician; hence, was not required to register, and could not be indicted as an illegal practitioner.

In the second place, the law, by the use of the words "now lawfully engaged" (Section 2), makes it

possible for regular physicians only to commit perjury. The irregular practitioner may swear falsely as to where and how he obtained his diploma, and yet the law seems to say he cannot commit perjury.

Nor does the law prevent a man who has been once indicted from practising under cover of selling medicines.

To remedy these defects, the President suggested the passage of a law obliging all future practitioners of medicine to prove their qualifications by a State examination, and by placing all the different schools upon an equal footing. One of the most serious obstacles to the securing of this would be public apathy, for which, perhaps, the medical profession was, to a degree, responsible. Distasteful as the confession might be, the public do not care very much about having educated physicians. Indeed, one grand juryman said that he did not see the necessity of a physician having any special education or diploma. Besides, the public think that these laws are only attempts of one sect in medicine to fight another, not reflecting that they are the ones who are most injured by the malpractice of ignorant pretenders. It rested with the individual members of the medical profession to correct these impressions.

In closing, the President expressed his thanks for the high honor conferred by electing so young a man to the presidential office, and said that he should spare no efforts to keep the work of the society up to the same standard in the future that it had obtained in the past.

The paper of the evening was read by Dr. A. B. Judson, and entitled

A PRACTICAL POINT IN THE MECHANICAL THERAPEUTICS OF HIP DISEASE.

The author gave a brief analytical consideration of the causes of the relaxation which has been noticed in the leathern straps at the lower part of the ordinary long hip-splint when the patient stands. The subject has been commented on by Drs. Hutchison and Schaffer, and others. The chief cause was found in the too light construction of the splint. It is difficult to induce an instrument-maker to furnish a splint sufficiently strong to meet the requirements of the case. It was demanded, however, by the interest of the patient. A strong and unyielding support would protect the joint from concussion in locomotion, by keeping the heel of the patient removed from the ground. It would further make the splint more efficient as a means of fixation or immobilization of the joint, which was considered by the author of the paper as one of the principal functions of this apparatus. To further aid in preventing the lower straps from becoming loose, stout perineal bands should be used, and a low pelvic band below the anterior superior spinous process, which afforded points of attachment more nearly on a level than when the high pelvic belt was employed.

Dr. Schoenemann alluded to the fact that many surgeons went to the instrument-maker and simply took and endeavored to use whatever instrument was offered them, and of course failed in their efforts to treat the case. The reason for the failure consisted in the fact that a proper appreciation of the end to be attained, and the means by which it was to be secured, was not always borne in mind. Attention to minor details gave success. He regarded the physiological treatment as valueless in synovitis of the hip-joint, while it might be serviceable in some other cases; therefore the importance of correct diagnosis. With reference to traction to afford rest to the inflamed joint, only so much was required as was necessary to overcome the power of the muscles.

Dr. Lewis A. Sayre remarked that he had adopted the physiological treatment of hip disease in sixty or seventy cases, and for himself, at least, had demonstrated that the plan had no practical value whatever. He was attracted at first, because of its apparent reasonableness and its actual simplicity; but it had not stood the practical test.

With reference to the splint, with its pelvic band, perineal straps, etc., he thought if the column of weight was borne upon the perineal straps, it made no difference should the extension-straps be more or less loose, for the amount of traction necessary was not very great after all. The amount of traction necessary was only that required to make the patient perfectly comfortable, and as soon as it was applied in the line of the deformity, a very small amount answered all indications, and more was very liable to damage.

With reference to keeping up extension, and at the same time allowing motion in an inflamed joint, he knew the statement made by Dr. Agnew in his recent work on surgery, that it was an impossibility, was not true. Extension was necessary to prevent interstitial absorption produced by pressure resulting from reflex muscular contraction, which held the inflamed joint surfaces in close contact with each other, and the requisite amount could be secured by various splints now in common use, and at the same time permit motion in the joint, and thus prevent anchylosis. The essentials were a fixed perineal pad, which would receive the weight of the body, transferred from the joint to the perineum, and only such an amount of extension as was necessary to render the patient perfectly comfortable, and prevent the inflamed surfaces from rubbing against each other.

Dr. M. Josiah Roberts thought the theory advanced by the author of the paper was correct when studied from a mechanical point of view. The immobility, regarded by Dr. Judson as essential, could be better secured by lowering the pelvic belt and narrowing the space between the points of attachment for the extension-straps. With reference to the indication, however, in the mechanical therapeutics of hip disease, there was room for difference of opinion.

Dr. Malcolm McLean thought the mistake was very frequently made of applying too much extension in the treatment of joint-affections. The amount necessary was simply that which was sufficient to keep the muscles quiet.

Dr. Judson said that he did not apply extension and counter-extension with the view to counteract the articular muscles so much as to secure *fixation* of the joint, and to that end it was only necessary to secure with the rack and pinion that fractional degree of fixation which would secure perfect comfort for the patient, and facilitate his recovery.

The society then adjourned.

---

The Hospital for Oral Surgery in Philadelphia is an institution which is calculated to develop dentistry into a genuine surgical specialty. The Hospital gives certificates of qualification to practise this branch only to persons who have studied dentistry, have received a medical degree, and have made some special study of the surgery of the mouth.

## MATERIA MEDICA SOCIETY.

*Stated Meeting, October* 27, 1881.

DR. PIFFARD, PRESIDENT, IN THE CHAIR.

### ADJUVANTS AND CORRIGENTS.

A PAPER on "Adjuvants and Corrigents" was read by DR. CASTLE (*vide* p. 647).

In discussing the paper, DR. SEXTON stated that he had been accustomed to use nitrous oxide gas for the relief of asthma. Its marked stimulating effects had suggested to him the desirability of employing it in combination with chloroform, to counteract the depressant effect of the latter agent. Besides possessing stimulating properties, it decidedly facilitated the action of chloroform. He had not followed up these experiments, but was satisfied that a combination of nitrous oxide, and perhaps other agents, with chloroform, would act admirably.

DR. BRONSON thought that the paper covered so vast a field, and embraced so many points of practical interest, that it would be impossible to discuss it properly at the present meeting.

DR. PIFFARD recommended that the paper be made a special order for some subsequent meeting.

On motion, it was resolved that the author of the essay be requested to have it published in the MEDICAL RECORD as soon as practicable, and that a copy of the journal be furnished to each of the members of the society.

In the general discussion which followed, DR. MORROW remarked that, while the author of the paper had shown the decided advantages sometimes derived from the use of adjuvants and corrigents, yet he was inclined to think that it was preferable, so far as practicable, to employ drugs singly rather than in combination. He thought that much of the uncertainty and confusion which attended the use of drugs was due to the multiplicity of the agents prescribed. In order to get definite and precise results in prescribing, the action of the principal drug or essential agent should not be masked or modified by combining it with others. Specific medication was the object aimed at in therapeutics. The more specific remedies were, the less did combination become necessary. Adjuvants and corrigents were not given to modify the effects of mercury in syphilis, of quinine in malaria, or the specific action of ergot, morphine, etc.

DR. SMITH said that professors of materia medica and therapeutics were, as a rule, quite prolific in formulæ, and accustomed to give prescriptions with numerous combinations. He, however, was an exception. He had that day seen a case in which the patient showed him the prescription the doctor had given him, containing eight or ten different ingredients. The more he advanced in practice, the more he felt inclined to give remedies singly.

DR. WEBSTER said that he had never been in the habit of giving many drugs in the same prescription, although, as a matter of course, he did not employ as large a number of remedies as the general practitioner. His armamentarium was small, comprising mercury and potassium iodide for syphilitic affections—the mercury he almost always used by inunction—codeia as an anodyne, or morphia, atropia, strychnia, and a few others.

DR. CASTLE said that while there was no doubt that progressive physicians were gradually eliminating superfluous drugs from formulæ and using single remedies, yet there were certain agents, especially narcotics, which it was desirable to use in combination. He recommended that morphia and atropia should always be used in combination. Dr. Harley had advised that when sedatives were used in conditions of weakened heart-action, respiratory stimulants should always be exhibited to counteract their depressant effect. Fothergill had pointed out the desirability of using respiratory stimulants in combination in certain conditions, and respiratory depressants in others. As of great importance, another point to be emphasized was the value of employing certain adjuvants to increase the activity of the organs through which certain drugs were normally eliminated.

A general discussion then ensued as to the properties and therapeutic value of the modified Warburg's tincture. Drs. Purdy, Castle, Smith, and Farnham participated.

The society then went into executive session.

## Correspondence.

### THE CONDITION OF THE ARTERIES AFTER DEATH.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: It is with great diffidence that I venture to differ on an anatomical question with so distinguished an anatomist and surgeon as my friend, Dr. William Hunt, of Philadelphia, but I cannot allow his criticism of me in the last number of THE MEDICAL RECORD to pass unnoticed.

Commenting on my statement (and that of Dr. Sims to a like effect), that the blood extravasated into the peritoneal cavity in President Garfield's case might have been pushed out by the injection of chloride of zinc solution used shortly after the death of the patient, Dr. Hunt says: "Have these gentlemen forgotten the very elementary principles and facts of their training as to the blood-vessels? Were they not taught that the very name 'artery' is a misnomer, and arises from the fact that the ancients found the arteries empty after death, and that the knowledge of their uses was not fully made out until the time of Harvey?

"Those who have spent years in the sculleries of dissecting-rooms and in the rooms themselves know practically that nothing is pushed out from *arteries* by injections, for a very plain reason: that there is nothing to push out."

To answer Dr. Hunt's questions categorically, I have only to say:

1. That I was very early in my student-life taught that the name artery is a misnomer.

2. That I was taught that the ancients from the time of Galen knew perfectly well that the arteries did not contain air, and that consequently we did not have to wait for Harvey to tell us this.

And I will add:

That I was also taught that the idea that all the arteries are found empty after death is erroneous, and that my own observation has convinced me of this fact.

If I had got my teaching entirely from the dissecting-rooms and their "sculleries," I might have been brought to believe that the whole arterial system became completely empty at the death of the individual; whereas it is a matter of fact that it does nothing of the kind. The arteries contract after

death, but the process does not begin immediately. They are therefore of smaller size than during life, and hence they contain less blood; but, as a rule, with the exception of the large vessels near the heart, they are full, and this is especially true of the splenic artery. This artery is, as my friend knows better than I do, remarkably tortuous, its coats are thicker than those of any other artery in the body, and it is the largest branch of the cœliac axis. Hence (particularly from the thickness of its coats), its calibre is not materially diminished after death, and it always contains a large proportion of blood.

It may not be out of place for me to state that several years ago, while in Philadelphia, enjoying, among the other pleasures of that delightful city, the scholarly companionship of my friend, I made a special study of the spleen, examining for this purpose the organ in over a thousand animals of various genera and species. Hence, I am tolerably familiar with it and its vessels.

But I do not wish to have the questions raised by Dr. Hunt depend upon my own opinion. I have, therefore, to "hurl" at him two or three authorities.

Müller,* speaking of the contractility of the arteries, as exhibited after death, says:

"They are, in fact, for the most part not quite empty, but contain as much blood as they are able to admit in their most contracted state."

And again:†

"It is not rare to find blood in the arteries after death."

Relative to the peculiarities of the splenic artery, I quote from Kölliker‡ as follows:

"The size of the splenic arteries is very considerable in proportion to that of the organ, and so also the thickness of their coats is worthy of notice. . . . . In the mammalia generally the splenic artery is proportionally smaller than in men. This possibly depends only upon the more considerable contraction of the vessel at their death. Wintringham finds that the thickness of the arterial coats is greater than that of the aorta above the giving off of the renal arteries, to which it bears the ratio of 1 to 0.762. He also states that they will sustain a pressure of forty-one pounds."

Dissecting-room subjects are not suitable for studies of the kind in question. Days, even months, sometimes elapse before they are examined. As soon as they are obtained a preservative fluid is injected into the vessels, and then perhaps a further injection for display purposes is introduced. In the case of General Garfield the chloride of zinc solution was injected at so short a period after death that there was not time for the arteries to contract to any considerable extent.

If my distinguished friend will only call to mind his anatomical knowledge, derived from his extensive hospital experience and the numerous post-mortem examinations he has made, and forget for the moment that which has come to him from the dissecting-rooms, I think he will agree with me that there was some warrant for my assertion that the extravasated blood in the President's case *might* have been poured out from the splenic artery after death. And I think also that, upon mature reflection, he will recall his opinion that the extraordinary and unscientific proceeding of injecting with chloride of zinc a body upon which the most important post-mortem examination of our times was to be performed was "a good thing."

WILLIAM A. HAMMOND.

NEW YORK, December 4, 1881.

## CONCERNING THE FINDING OF BALLS IN CAVITIES.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR: In the number of your journal for December 3, 1881, Dr. E. B. Turnipseed, of Columbia, S. C., expresses his belief that if the President's physicians had used his instrument for finding and extracting balls, which instrument he says "is yet unknown to the profession," they would have saved his life, and the nation would have been spared this great loss.

I have a word to say in reply to this afterthought of Dr. Turnipseed, and the equally untimely afterthoughts of a few other medical men, namely, that it is somewhat singular that not one of these gentlemen, who so grieve over the shortcomings of the late President's doctors, have ever in a single instance tried their methods upon a human being. They have no successes to record, no failures indeed, for the good reason that they have never put their methods to the test of experience; but, nevertheless, the President's doctors ought to have tried their methods, and if they had there is not a shadow of doubt in their minds that the President would have been alive to-day.

If none of the critics have sufficient surgical practice to enable them to try their plans of searching for and removing a bullet from the abdominal cavity, I wish to suggest what does not seem to have occurred to them, that they shoot balls into the abdominal cavity of a cadaver, and then determine by actual experiment whether they can track or remove a ball by the use of their ingenious devices. If it can be done on the living subject, they certainly will experience no difficulty in doing it upon the dead. Let such gentlemen, in the presence of four or five intelligent and honest surgeons, do this a dozen or more times and tell us the results, with full details as to the time occupied, etc. Dr. Turnipseed has had the instrument made by Mr. Tiemann, and it is all ready now for use. Suppose the Doctor with a few others try it, and, if he succeeds, it may save the life of the next president who is shot—provided, of course, some person sufficiently skilled in the use of surgical instruments is employed to treat the case, for such ingenious devices must not be held responsible for a failure when placed in the hands of such men as were employed in the case of the late President.

If the importance of the subject can justify a further occupation of space in your valuable journal, I would like to say a word or two more.

Dr. Turnipseed, before entering upon his criticism, uses the following self-deprecatory language: "I falter when I think of the grave responsibility and *my incapacity* for so great a task." In behalf of science I wish to protest against a sentiment so calculated to arrest or retard its future progress, namely, that "incapacity" should induce any man to hesitate in the expression of an opinion; and I am pleased to see that, notwithstanding this declaration as to his own qualifications as a critic, he does not hesitate to condemn the surgical treatment in the

case of President Garfield as bad from beginning to end. I may not, and others may not, agree with him, but it vindicates the principle of the right of every man to give an opinion, and it is in this way alone that science can make advances despite the narrow, unprogressive spirit of those who have only travelled the beaten road of experience. If certain things had been done with the aid of his new instrument, the case, he says, "would have probably resulted in recovery." "If ever the ball had been located any time during the President's illness, it would have been *unjustifiable and hazardous* to cut it out either from the front or rear (I think Hammond would express some doubt on this point), but I firmly believe that my bullet-forceps would have followed the *tortuous* track, seized and brought out the bullet at the point of its entrance. . . . I have a firm conviction that time and a full test of these instruments will prove the correctness of my assertions." A "test" may be necessary in the opinion of some gentlemen, but it is surprising to note that our author has convictions so strong that he has never thought it necessary to put himself to the trouble of making any sort of test.

It is due, Mr. Editor, to this sound cardinal principle of the right of every man, whether surgeon, physician, or layman, to speak his opinions freely, that so many have given to the doctors in attendance and to the public at large their valuable suggestions. It is seldom that any two agree in their suggestions or in their criticisms; but, so much the better, since there are now, perhaps, a thousand different ways in which it is known a valuable life might have been saved, while there might, if all had thought of the same thing, have been only one way. If, for example, all had thought only of the instrument in question, possibly it might not have been at hand when it was most needed.

I only wish to suggest, in conclusion, that it is sincerely to be hoped, in the interests of medical science, that some one hereafter, at a proper time, will gather into one volume—or a dozen volumes, if necessary—all the plans of treatment which would, beyond a question, have saved the life of our late President, including the plans proposed by newspaper editors, medical men, and the thousand or more suggestions contained in letters written to the doctors while they were in attendance upon their distinguished patient. Who can estimate the value of such a contribution to medical science and to humanity? Yours very respectfully,

L. DAMAINVILLE, M.D.

245 WEST FIFTY-SECOND STREET,
New York, December 5, 1881.

A CASE OF SLOW PULSE.—Dr. J. Baranowitz, of Farmingdale, N. Y., sends us the following history: "Mr. Henry Green, of this place, is a small, thin man, in good health, and of very phlegmatic temperament. Two years ago he came under my observation, afflicted with strangulated hernia of several hours' duration. He was in great pain and very anxious. Feeling his pulse, I found it to be at 40 a minute. The operation was unusually delayed; just before it he was very restless, suffering severely, with a temperature of 103° and a pulse of 64, which was the highest observed. Within four days after the operation it came down to 40 per minute.

"I requested the gentleman to step into my office to-day, November 15th, when I made the following observation: In recumbent position, 42; sitting, 43; standing, 45. Heart otherwise normal."

## ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from November 27, 1881, to December 3, 1881.*

HALL, WILLIAM R., Capt. and Asst. Surgeon. The leave of absence granted him in S. O. 224, Department of the Missouri, November 2, 1881, is extended fifteen days. S. O. 120, Military Division of the Missouri, November 25, 1881.

CORBUSIER, WILLIAM H., Capt. and Asst. Surgeon. Granted leave of absence for four months. S. O. 266, A. G. O., November 25, 1881.

DAVIS, WILLIAM B., First. Lieut. and Asst. Surgeon. Granted leave of absence for four months. S. O. 269, A. G. O., November 29, 1881.

STRONG, N., First Lieut. and Asst. Surgeon. Relieved from duty at Fort Douglas, U. T., and assigned to duty as Post Surgeon at Fort Cameron, Utah. S. O. 121, Department of the Platte, November 26, 1881.

TAYLOR, A. W., First Lieut. and Asst. Surgeon. Assigned to duty at Fort Supply, Ind. Ter. S. O. 246, Department of the Missouri, November 29, 1881.

CARTER, E. C., First Lieut. and Asst. Surgeon. Assigned to duty at Angel Island, Cal. S. O. 203, Military Division of the Pacific and Department of California, November 22, 1881.

RAYMOND, HENRY I., First. Lieut. and Asst. Surgeon. Assigned to duty at Alcatraz Island, Cal. S. O. 203, Military Division of the Pacific and Department of California, November 22, 1881.

## Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT. — **Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending December 3, 1881.**

| Week Ending | Typhus Fever. | Typhoid Fever. | Scarlet Fever. | Cerebro-spinal Meningitis. | Measles. | Diphtheria. | Small-pox. | Yellow Fever. |
|---|---|---|---|---|---|---|---|---|

| Dec. 3, 1881. | 0 | 43 | 220 | 2 | 84 | 93 | 33 | 0 |

BLINDNESS IN SPAIN.—The above is the title of a treatise read by Dr. Carreras-Aragó at the inaugural session of the Academy and Laboratory of Medical Sciences of Catalonia. According to his statistics, the proportion of the blind in Spain, as a whole, is 10.78 in 10,000 inhabitants. The minimum proportion exists in the provinces of Zamora and Palencia, 2.49 in 10,000; the maximum, in Cordova, is 22.44 in 10,000. After presenting the figures obtained in the various provinces, the author classifies his cases according to sex, age, and condition. A careful and conscientious study of his subject has enabled him to produce interesting data in regard to the etiology of blindness. He has observed the important differences in the geographical conformation of the various sections of the country, the conditions of the soil, the occupations of the inhabitants, etc. The

dryness of the soil, the intensity of the sunlight, certain occupations, such as the cultivation of rice, hemp, flax, rye, the want of cleanliness, and the lack of education, the geographical situation of the various provinces, are all factors in the production of blindness. In regard to the affections bringing about this condition, Dr. Carreras-Aragó presents the following figures: Out of 1,000 cases, 61 were due to structural anomalies, 56 followed purulent ophthalmia of the new-born, 91 resulted from granular ophthalmia, 43 from small-pox and various other exanthemata, 96 from glaucoma, 111 from affections of the cornea and iris, 210 from affections of the choroid and retina, 241 from affections of the optic nerve and cerebro-spinal trouble, and lastly, 91 were due to traumatisms.

Œnas Afer as a Vesicant.—In the *Siglo-medico*, Prof. Armengué, of Barcelona, details several experiments which lead him to recommend the œnas afer as a vesicant. The preparation is said to be prompt and certain in its action, and never painful. In every case the insensibility was extraordinary. The serum was clear and abundant, except in one case, in which it was bright yellow. No genito-urinary symptoms were produced, perhaps on account of the small quantity employed. The œnas afer is an insect which is quite common in certain parts of Spain. The author thinks it should rank higher than, or as high, as the cantharis.

The New York Society for the Relief of Widows and Orphans of Medical Men.—The thirty-ninth annual meeting of the society was held at the New York Academy of Medicine, on Wednesday evening, November 23d. In the absence of the President, Dr. William Detmold was called upon to preside.

The society proceeded to its annual election, which resulted as follows: *President*—Dr. Jared Linsley; *Vice-Presidents*—Drs. Isaac E. Taylor, Thomas F. Cock, Samuel S. Purple; *Treasurer*—Dr. John H. Hinton; *Managers for a term of three years*—Drs. James L. Banks, Gouverneur M. Smith, Joel Foster, T. C. Finnell, J. W. Warner, Alfred C. Post, and John J. Milhau.

The society has extended aid to twelve widows and four children of deceased members during the year. Two annuitants have recently been added, and will draw their first annuities on January 1, 1882. From the printed annual statement it appears that the total assets of the society amount to $135,459.68, chiefly invested in bond and mortgage.

The Ninth Annual Meeting of the American Public Health Association.—At the second day's sessions the following papers were read: "Inside Sources of Disease," by Dr. J. J. Speed, of Kentucky; "A History of Sunstroke Mortality in 1881," by Dr. A. J. Miles, of Ohio; "Malaria in New England," by Dr. J. F. Adams, of Massachusetts; "The Duties of the Citizen to the State in Maintaining Public Health," by the Hon. Erastus Brooks, of New York; "School Hygiene," by Dr. H. Isaac Jones, of Scranton, Penn.; "The Pernicious Effect of Tobacco on Youths," by Dr. Albert C. Georgas, of the Navy; "Fraternity Among Scientists," by Dr. Louis A. Falligant; "The Yellow Fever Epidemic of 1878," by Dr. C. B. White, of the Sanitary Association, the paper being read by Dr. Gustavus Deveron, of New Orleans; "Impure Water and Its Dangers," by Dr. Moses J. Runnells, of Indiana; "The Atmospheric Element in Local Epidemics," by Dr. T. C. Duncan, of Illinois; "Railroad Sanitation," by Dr. S. S. Herrick, of Louisiana; "The Control of Defective Sight on Land or Sea," by Dr. B. Joy Jeffries, of Massachusetts; "Health the True Nobility," by Dr. Albert L. Gihon, of the United States Navy. In the morning the association participated in an excursion down the harbor, tendered by the citizens.

On the last day an amendment to the constitution was passed making the Second Vice-President a member of the Executive Council. There was an animated discussion on a resolution to get State representation in the National Board of Health, which ended in the resolution being defeated. The following papers were read: "The Relations of State and Local Quarantine Systems to a National Quarantine System," by Dr. Stephen Smith, of New York; "The Origin and Progress of International Hygiene," by Dr. James L. Cabell, of Virginia; "The Prevention of Insanity," Dr. Charles F. Folsom; "Malaria in Connecticut," Dr. C. W. Chamberlain; "Observations on the Potomac Marshes as a Pathogenic Agent in the Production of So-called Malarial Fevers," Dr. A. G. P. Garnett; "Some Remarks upon National and International Sanitary Jurisprudence," Dr. Thomas J. Turner; "Two Suggestions Concerning Healthful Buildings," Dr. W. C. Van Bibber. A resolution to change the character of the Advisory Committee was voted down. The usual resolutions of thanks were then passed, and the convention adjourned *sine die*.

Dr. Ferrier Indicted by the Anti-Vivisectionists.—The English Anti-Vivisection Society has brought an indictment against Dr. Ferrier for vivisecting contrary to law. The action is based on the report of Ferrier's experiments before the Physiological Section of the International Medical Congress. At that time the defendant exhibited a monkey which he had trephined and made certain experiments upon in cerebral localization.

The "Popular Science Monthly" and Quack Advertisements.—A correspondent from Norwich, Conn., writes: "Some time ago I noticed with satisfaction your editorial on the subject of patent medicine advertisements in the religious press, and I find that your remarks on the subject had the effect of shaming some of the better class of religious periodicals. However, we know that the testimonials of the clergy are always prominent among the many appended to the advertisements of patent medicines, and it is not strange that the ministerial editors of the religious press should not be loth to turn an honest (?) dollar by giving their sanction to 'the fair Lydia's' antimechanical treatment of uterine displacements, and 'the only sure cure for catarrh.' But I desire to call your attention to a case which, to my mind, is far more reprehensible. Some months ago, in reading over the advertisements in a *scientific* monthly, intended for popular use, I was surprised to find that a page was devoted to the claims of a 'cure-all' blood compound. The fact of the advertisement being in such a periodical, supposed to be read only by those interested in scientific work, and flanked by an advertisement of scientific apparatus for sale, or an announcement of the publication of some of Herbert Spencer's works, struck me as rather peculiar, to say the least. This month's number (November) has, on two pages facing each other, no less than five evidently false advertisements—a 'cure for fits' (kind not mentioned), a 'sure cure for consumption,' somebody's pills to cure most anything, a long catch advertisement of a

liniment, and a cure for deafness. Turning over the page, we have another somebody's pills, and the kidney cure that we see everywhere. Alongside of these I find the announcement of an excellent medical work by one of your leading authorities in New York. Sandwiching in this way the advertisements of medical books and patent medicines I think is in anything but good taste. The editors of the *Churchman* and *Christian Union* MAY not know any better than to believe in a sure cure for consumption; the editors of the *Popular Science Monthly* MUST. The *American Agriculturist* says, in its advertising rates, 'No room for patent medicines and humbugs.' I would suggest that it would elevate the tone of the *Popular Science Monthly* if it should do the same."

THE NEW BALTIMORE MEDICAL COLLEGE has issued its first announcement. It says that it appears in no spirit of opposition to other schools, but rather to encourage and stimulate them to increased efficiency. It will seek to elevate the standard of medical education, professionally and morally, and covets the reputation of becoming a practical "Christian Medical School." It admits persons of both sexes. Its prospects of success seem to be founded on its religious and co-educational principles. The gentlemen composing the faculty have a good professional and social standing. With but one or two exceptions, none have achieved any especial eminence in medical or surgical science. The following are the faculty: Harvey L. Byrd, M.D., President and Professor of Obstetrics and Diseases of Women and Children; W. Robert Munroe, M.D., Professor of Materia Medica, Therapeutics, and Hygiene, Dean; Benjamin F. Leonard, M.D., Professor of Physiology, and Clinical Professor of Diseases of the Rectum; Henry Froehling, M.D., Professor of Chemistry, Toxicology, and Medical Jurisprudence; L. Wheaton Clapp, M.D., Professor of Principles and Practice of Medicine; John R. Uhler, M.D., Professor of Principles and Practice of Surgery and Physical Medicine; L. Robert Coates, M.D., Professor of General, Descriptive, and Surgical Anatomy; Adolph G. Hoen, M.D., Lecturer on Histology.

YELLOW FEVER IN THE UNITED STATES DURING THE PAST YEAR.—In the annual report of the National Board of Health, just published, it is stated that the only locality in the United States in which a case of yellow fever has occurred on shore during the summer is said to have been at Key West. The report goes on to say: "That the station at Ship Island and other similar stations which the board intended to establish, may justly be characterized as 'adequate safeguards' against the introduction of infectious diseases into any of the ports of entry which will co-operate with the National Board of Health in its efforts to secure such a result, seems to be sufficiently attested by the experience of this summer. Four yellow fever ships have been received and treated at Ship Island during the summer, the same having been sent thither by the quarantine authorities of Pensacola, Mobile, and Pascagoula. No death has occurred among the cases received in hospital, and no case of fever has occurred upon either of the vessels after they were released, or in any port where they have subsequently touched."

PICROTOXINE AND HYDRATE OF PICROTOXIDE.—Chirone (*Annali Univ. di Med. e Chir.*) reports numerous experiments made upon fishes, reptiles, birds, mammifers, and inferior animals. His researches lead him to assert that there is a difference in action between picrotoxine and the hydrate of picrotoxide, both of which are derived from the same plant, the *cocculus indicus*. The hydrate of picrotoxide is much feebler than picrotoxine, and may be used for the latter, which is thirty times as powerful. 1st. The hydrate of picrotoxide, called by Barth and Kreschy picrotine—they believing it to be bitter, but not poisonous—does not merit this latter appellation, because it is not only bitter, but has toxic properties also. 2d. The toxic power of the hydrate of picrotoxide is to that of picrotoxine as one is to thirty, approximately. 3d. The epileptic convulsions determined by the hydrate of picrotoxide, with slight differences, are analogous to those caused by picrotoxine. 4th. The difference between the two morbid forms may be reduced to the following characteristics: convulsions caused by the hydrate of picrotoxide affect either not at all, or very slightly, the ball of the eye; rather produce emprosthotonus than opisthotonus; affect rather the muscles of the extremities than those of the back; after death cadaveric rigidity comes on suddenly. 5th. The hydrate of picrotoxide, as well as picrotoxine, determines epileptic convulsions, acting upon the bulbar and spinal motor centres, so that its action is best seen, and in its greatest intensity, in decapitated frogs and in pigeons whose cerebellum has been removed. —*Riv. Clin. di Bol.*, August.

SUDDEN DISLOCATION OF THE LIVER, WITH RECOVERY.—Dr. Alexander Y. P. Garnett (*American Journal of the Medical Sciences*, January, 1881), reports, apparently, the only case of sudden dislocation of the liver, on record. A lady, aged fifty, while stooping down hurriedly to pick something from the floor, "felt a sudden wrench or giving way on the right side." Examination revealed a displaced liver reaching to the crest of the ilium. Much discomfort was experienced, but the patient was relieved by spontaneous reduction in the space of three days. A week's confinement in bed, followed by the use of a broad elastic band around the waist, constituted the necessary remaining treatment. The patient apparently regained, to a great extent, her normal condition and state of health.—*Chicago Medical Review.*

DR. T. LAUDER BRUNTON, editor of *The Practitioner*, has ventured into popular literature and written a work, entitled "The Bible and Science." It is published by Macmillan and has received very commendatory notices.

SMALL-POX RAVAGES IN CHICAGO.—Of 1,359 cases of small-pox in Chicago since January 1st, forty per cent. have proved fatal. It is noteworthy that by far the greater number of cases have occurred in those districts where the more degraded portion of the foreign element lives, and where attempts at vaccination have been met by open violence at times. In that portion of the city there are 40,000 persons who have not been vaccinated, and of the 108 deaths in September 81 occurred among these. It is believed that the publication of these facts will create such a sentiment as will result in almost universal vaccination and in increased diligence in the matter of cleaning the streets.

THE COLLEGE OF PHYSICIANS AND SURGEONS OF CHICAGO is the name of the new medical college organized at Chicago. The incorporators are Dr. A. Reeves Jackson, Dr. C. Warrington Earle, and Dr. A. K. Steele.

## KUMYSS.

By E. F. BRUSH, M.D.,

FELLOW OF THE NEW YORK ACADEMY OF MEDICINE, MEMBER OF THE WESTCHESTER COUNTY MEDICAL SOCIETY, ETC.

Historically the study of kumyss is very interesting. Homer speaks of the kumyss making Hippomolgi; we are justified in calling them kumyss-makers, as Herodotus, describing the same northern tribes, tells us that the Scythians deprived their slaves of sight, in order to keep secret the process of making a drink from mare's milk. Virgil, to come down to the commencement of our era, sings of the tribe:

"Qui lac concretum cum sanguine potat equino."

The line, of course, may be interpreted to mean that whey was the potation; but, as all other authors who allude to a beverage made from mare's milk, leave no doubt that it was a vinous fermentation, we may infer that Virgil meant the latter. Descending to still more recent times, Father de Robinquis, who was sent as an ambassador to the East by Louis IX. of France, in the year 1253, gives a very accurate description of the manufacture of kumyss. The most remarkable fact in his statements is that regarding the quantity of the product—one chief whom he met receiving daily that made from the milk of a hundred mares. Marco Polo, the great Venetian traveller, writing a few years later, speaks of kumyss as a common drink, wholesome, nutritious, and possessing important medicinal properties. Pallas, who was sent by the Empress Catharine II. to visit the less-known portions of her dominions, and who is still one of our best authorities, gave considerable attention to the question of kumyss. He writes (vol. i., p. 507, Paris ed., 1788) as follows: "As few mares give milk in winter, the Calmucks are obliged to content themselves, during that season, with that of the cow. They unanimously say that it is less spirituous than that of the horse." This remark sufficiently disproves the opinion of those recent newspaper writers who describe kumyss made from cow's milk as an imitation. He gives an account of the process of manufacture, in these words: "To sour the milk they pour it into large leathern vessels, and place them, in winter, near the fire. The condition of these vessels often of itself suffices to sour the milk. They use also leaven made of coarse flour, very salt. They add, sometimes, some of the last fermentation, or curdled milk, from the stomach of a lamb. They do not cream the milk; but, on the other hand, they employ a dasher, but this only in winter, as in summer they put the milk into skin-bags, which they shake two or three times a day." The above statements of Pallas apply to the Calmuck tribes; but as all the other Tartar tribes, the Crim Tartars, the Usbeks, the Nogai, the Kirghis, and others, all prepare it, there exists considerable difference in their methods. Until recent years it was not known that kumyss was made except among these tribes. The habits of these people show clearly why they are the sole kumyss-makers. They are nomadic, lazy, neglectful of agriculture. Their wealth consists in herds of mares, the milk of which cannot be manufactured into cheese or butter, and which, owing to the large quantity of sugar it contains, ferments spontaneously. This they undoubtedly discovered by attempting to preserve the milk, for a day or two, in skin-bags. From this step it is a short one to the discovery that the longer it was kept the more pleasant it became. Mrs. Guthrie, who visited the Crimea in 1795, writes: "On stopping at a village, the hospitable Tartars brought us a wooden dish of their favorite kumyss. The kumyss has a sourish-sweet taste by no means unpleasant to my palate. . . . But to return to our mare's milk. That fluid has long been known to yield an ardent spirit. But Pallas tells us that in his travels he met a horde of Tartars who possessed the secret of turning cow's milk into vinous fermentation, or, in other words, of converting it into kumyss." The account of Dr. Clarke, in his Russian travels, is too well known to need quotation, and gives us very little satisfactory information. Atkinson, in his "Oriental and Western Siberia" (p. 280), gives a woodcut of a group of Kirghis with kumyss-bottle and bowl, and describes the dwelling of a great and wealthy chief in the steppe. "In another part of the *yourt*," he writes, "is the large leathern kumyss-sack, completely covered up with blankets to keep it warm and aid the fermentation. This is a most important piece of furniture in a Kirghis domestic establishment. I have seen one five feet eight inches long and four feet five inches wide, with a leathern tube in one corner, about four inches in diameter, through which they pour the milk into the bag, and draw the kumyss out. A wooden instrument is introduced into the bag, the handle passing through the tube, not unlike a churning-staff. With this, the kumyss is frequently agitated. The bag is never washed out; it would be spoiled by doing so. Near the kumyss-bag stands a large leathern bottle, sometimes holding four gallons, often highly ornamented, as are the small bottles made to carry on the saddle.

"On entering a Kirghis *yourt* in summer, a Chinese bowl holding three pints of kumyss is presented to each guest. It is considered impolite to return the vessel before emptying it, and a good Kirghis is never guilty of this impropriety. They begin to make kumyss in April. The mares are milked at five o'clock in the morning, and the same hour in the evening, into large leathern pails, which are immediately taken into the *yourt* and the milk poured into the kumyss-bag. The first fourteen days after they begin making this beverage, very little of it is drunk, but, with fermentation and agitation, it is considered by this time in perfection, when it is drunk in great quantities by the wealthy Kirghis, as a man must have a large stud of brood-mares to afford a corresponding consumption of the beverage. Almost every Kirghis has a kumyss-bottle slung to his saddle, in summer, which he loses no opportunity of replenishing at every *aoul* he visits." I have quoted Atkinson at this length to avoid the necessity of quoting from our medical authorities, Dahl and Neftel, any accounts of the habits of the Kirghis, and the mode of preparation, as I wish to extract from them simply their statement as to its therapeutic value. In an official report to the Russian Government, in 1840, Dr. W. F. Dahl, after describing the people and their method of manufacturing kumyss, continues: "Peculiar as is the taste of kumyss, one soon becomes accustomed to it, especially if one tastes it for the first time when thirsty, or after violent exercise. It is then the most pleasant and refreshing of all drinks. The peculiar odor of kumyss is offensive to some persons; but, if it is tasted under the circumstances just mentioned, no one will ever abandon it for any other sort of drink whatever. It is very refreshing

and hunger-stilling, without being surfeiting. It only allays hunger without destroying the appetite, so that one can pass a long time without other food, and can also, while taking kumyss, eat just as much as at other times. Kumyss, too, has one very peculiar property which is difficult to explain, but which is confirmed by repeated experience: it is never surfeiting. One can, without any fear, drink as much as he will — an inconceivable amount — and yet always feel light and well. If one were to drink half the quantity of water, beer, or anything else, especially during the burning heat when one is forced to be on horseback, one would feel heavy, overfull, and weary. But every cup of kumyss gives new courage and strength. An intoxication such as is produced by wine never takes place after drinking kumyss, in whatever quantities you may; the result is a scarcely noticeable exhilaration, and this only when it is taken in very considerable quantities, or, in delicate persons, when it produces an inclination to a refreshing sleep . . . . The first feeling after copious draughts is costiveness, without any other inconvenience or loss of appetite. The stool regulates itself in the course of a few days, but there is always a tendency to obstruction, and the excrement is hard and less abundant than usual. The urine at the same time alters in quantity and quality; it is less abundant than usual, and generally discolored, with a strong sediment. It is remarkable how disproportionately slight the amount of urine is in comparison with the quantity of drink taken. Kumyss is, among the nomads, the drink of all children, from the suckling upward, the refreshment of the old and sick, the nourishment and greatest luxury of every one. The secondary effect of kumyss shows itself in less than a week in a good nourishment of the whole body, an increase in strength and spirits, and a general feeling of health. The respiration is easier, the voice freer, the complexion brighter; the faces which have become pallid and pinched in winter are scarcely to be recognized in spring, so sudden is the transformation to a healthy appearance. It is, however, very doubtful whether any nourishment, after such long fasting, hunger and short provisions, as the nomads endure during the whole of winter, would be suitable to their weakened frames or be able to restore them so quickly. After violent fatigues and hunger borne nobly for weeks, the Kirghis are careful to avoid excess of solid food, but indulge without fear in bags of kumyss.

"The diseases in which kumyss is beneficial are those where the body must be well nourished without loading the digestive organs. It seems, too, that kumyss is specially useful in chronic affections of the chest, not only in diseases of the lungs, but also of the bronchia and larynx. I will not assert that it can cure consumption and phthisis, but it suits these conditions better than any other nourishment, and may, even when the tendency is pretty well advanced, prevent the disease, especially if the cure can be kept up all summer, or if not prevent, at least delay it for some time. It is certain that among the Kirghis consumption and phthisis are very rare — much rarer than elsewhere; so, too, pneumonia, senile asthma, and dropsy of the chest. Of tubercular, pituitose, and other phthisis, I have seen no example among the Kirghis." Dr. Neftel, of this city, who in 1857, that is, twenty-three years after the visit of Dr. Dahl, was also sent by the Russian Government to the Kirghis steppe, in the district of Orenburg, confirms the observations of his predecessor. "Scrofulosis and rachitis are quite unknown among them; and, what is still more remarkable, I had opportunity to observe not one single case of lung-tuberculosis, although I sought for such cases with the greatest attention." To avoid repetition I will simply cite one case given by Dr. Neftel relating to kumyss treatment. "The patient, twenty-five years old, had always lived at St. Petersburg. Her physician there, a distinguished diagnostician, found tubercular infiltrations in both superior lobes of the lungs. During two years she coughed continually, with a muco-purulent expectoration often tinged with blood, and she became very emaciated. All other physicians consulted by the patient confirmed this diagnosis. During her first pregnancy the appearances of tuberculosis moderated, and the general condition improved; but, immediately after confinement, all the previous symptoms appeared with greater violence. The presence of cavities was clearly demonstrated, and a hectic fever set in. In this condition, the patient, by my advice, left the city, passed the whole summer in the steppe in a *kibitka*, and was methodically treated with kumyss. Her general condition gradually improved, and when she returned to the city in autumn she found herself nearly as before the pregnancy. The ensuing spring she again commenced the kumyss treatment, and I have lately received, here at Würzburg, a letter from her husband, in which he informs me that his wife is completely cured, and even coughs no longer."

The most recent article on kumyss has been written by Dr. A. M. Campbell, of Mount Vernon, N. Y., in the *American Journal of Obstetrics*, October, 1880. His observations are limited to the study of kumyss in cholera infantum. He reasons as follows: "In a severe case of choleraic diarrhœa we derive but little aid from medication, the primary cause of the disorder being the food put into the child's stomach. These cases occur almost exclusively among fed children. Our aim is chiefly directed to finding something on which the infant can be nourished, and which will not increase the trouble already existing. In kumyss we have a food which children with high temperature not only take kindly, but crave, its slightly acid taste being grateful to their parched tongues. It is an absolutely non-putrefactive food, is free from sugar, and is rarely rejected even by the most irritable stomach." After citing four cases successfully treated—cases, the types of many others—he continues: "Although I do not claim that kumyss is a panacea for every case of choleraic diarrhœa, I can say that we have in it a valuable aid with which to treat this most formidable complaint. . . . Its use in the early stages will aid in arresting the disease, by supplying nourishment which the infant can retain, and which will be readily absorbed. I can say for it that it has never failed me in any case of cholera infantum, except some in which well-marked brain-symptoms already existed, before it was administered, to such a degree as to preclude the possibility of a recovery. Even in these cases, it is an advantage, for we are giving a food which will not be vomited, and which will satisfy thirst."

Since the year 1875 I have been directing my attention to the study of milk, especially that of the cow, as an article of human food. My investigations naturally led me to the observation of kumyss, and I was much struck with the statements given by various travellers as to its therapeutic effects. Impressed with a conviction of its value in dietetics, I proceeded to make some experiments in producing it. The chief difficulty I found in the fact that mare's milk could not be obtained in sufficient quan-

tity for the purpose, while all the best kumyss of the Tartars is prepared therefrom. I sought consequently to ascertain the difference between the milks of the cow and of the mare. This again led me to form a classification which had never previously been made, namely, between the milk of the cud-chewers and that of the non-cud-chewers. I found that the former contained more caseine and of a different nature, more fat, and less sugar. The difference in the caseine of the cud-chewer from that of the non-cud-chewer is that the former variety coagulates into a hard, rubber-like mass under the action of acids and of the digestive ferment, while that of the latter, under like conditions, never forms the large coagulum, but is precipitated in fine, easily diffusible flakes. From this, therefore, it follows that, to render the milk of the cow similar in its constituents to that of the mare, we have, first, to increase the amount of milk-sugar; secondly, to decrease and modify the caseine. I do this as follows: to a given quantity of milk I add four per cent. of milk-sugar; take one-third of the milk, precipitate from it the caseine, and add the resulting whey to the milk I had taken it from; then, to make with this the kumyss, I add a proper ferment, and during the coagulation of the caseine the fermenting mass is constantly kept in a state of agitation, which breaks up the caseine and leaves it in the condition which it presents in the milk of the non-ruminant animals. I can say, for this preparation, that those who have been acquainted, by experience, with the Russian kumyss, declare that it is identical with the latter in all respects, except in the creosote odor which the Russian product derives from the smoke-stained skins in which it is manufactured and preserved.

It is quite needless for me to cite in detail cases illustrative of the benefits of kumyss as a food. In cases occurring where defective nutrition is a predominant feature, kumyss, with the exception of one or two isolated instances, has never failed in improving nutrition.

Mount Vernon, N. Y.

## CARBOLIZED CATGUT SUTURES FOR LACERATIONS OF THE CERVIX UTERI.

By A. REEVES JACKSON, A.M., M.D.,

Chicago, Ill.

During the past six years I have used as suture material, in the operation for the repair of lacerations of the cervix uteri, silver wire, silk, gut of the silk-worm, and carbolized catgut. As a result of this experience, I can confidently recommend the latter substance as being far superior to either of the others for the purpose indicated.

In my earlier operations I employed silver wire exclusively, and the results were wholly satisfactory so far as maintenance of coaptation of the parts and freedom from irritation were concerned. It had this drawback, however, to its usefulness—a second operation was always necessary for the purpose of removing the stitches. This involved the aid of one or two assistants, the procedure was attended by more or less pain, and was frequently dreaded by the patient almost as greatly as the original operation.

I next tried silk. This I found to be more manageable than wire, and I was enabled by its use to complete the operation more quickly. With the exception that it produced some slight and unimportant ulceration at the places of the sutures, it gave equally good results with the wire, and its removal was attended by less pain.

But I wanted something that would obviate the need for the secondary use of scissors and forceps, and in my quest I was deluded by the beauty of the silk-worm gut, and the hope that, being an animal substance, it might dissolve and disappear without assistance. But it did not. In one instance I permitted it to remain nearly four weeks, at the end of which time it appeared to have undergone no change, and I removed it as though it were wire. It was as easily adjusted as silk, and as capable of being firmly knotted, while, at the same time, it produced no more irritation than wire; but it presented no material advantage over either of those substances.

Finally, I ventured to try catgut; not wholly, at first, for I feared that, from its well-known solubility when imbedded in the tissues and fluids of the body, it might not retain the parts in apposition sufficiently long for union to take place. I therefore placed the animal sutures alternately with others of wire. On removing the latter, on the tenth day after operation, I could find no trace of the gut threads. Union was perfect. Subsequently, in another case, I used wire on one side and catgut on the other. On the eighth day following, I discovered only a few softened shreds of the latter. The union of the parts was equally complete on either side, and there was less appearance of redness on the side which had been closed with the catgut than on the other in which silver was used.

Latterly—for more than a year—I have been using catgut almost exclusively; and in no instance has it failed to hold the denuded surfaces together until firm adhesion has occurred. Having performed this function, it melts away and disappears, giving no trouble either to patient or surgeon.

But, in order to obtain such desirable result, I would caution the inexperienced operator that great care must be taken in paring the flaps. This must be done in such direction, and to such extent, as to permit the opposing surfaces to be brought *very easily* together; otherwise, the resulting swelling will cause any suture to "cut" more or less, and failure may ensue.

By immersing the catgut in warm water a few minutes before using it, it becomes almost as pliable as silk and can be as readily tied. I always make a triple knot.

While I consider the use of catgut as superior for the suture to either wire or silk in all ordinary cases of lacerated cervix, it is especially indicated in those in which repair of the torn perineum is likewise required; for both operations can then be done at the same time without making occasion for jeopardizing the new perineal adhesions by putting them on the stretch for the purpose of removing the stitches from the cervix. In the use of wire or silk we must either do this, or accept the alternative of waiting several weeks for the perineal structures to safely bear such strain; a delay obviously objectionable, especially to the patient.

271 Michigan Avenue.

Homœopathy and Babies.—"Have you seen my daughter's new baby?" asked a proud grandmother of her neighbor. "Yes, it is a handsome baby—but how very small it is!" "Oh, that's not surprising. The doctor who attended her was a homœopathist."

## LARYNGEAL GROWTHS.

By WHITFIELD WARD, A.M., M.D.,

PHYSICIAN TO THE METROPOLITAN THROAT HOSPITAL, NEW YORK.

Among the great variety of cases constantly presenting themselves to the special worker, none afford more interest than those of laryngeal neoplasm, and although these tumors are not infrequently met with by the laryngoscopist, they are so rarely seen by the busy general practitioner that their occasional illustration will be of sufficient interest to warrant publication. Of the several varieties of laryngeal growths, the papillomatous furnishes fully nine-tenths of the whole number, the remaining portion being represented by the epitheliomatous, the fibromatous, the sarcomatous, etc. The principal points of interest regarding interlaryngeal formations are three-fold: *First*, the nature of the tumor; *second*, its size; and, *lastly*, its location and attachments. The papilloma can nearly always be easily diagnosed by the skilled examiner, while the differentiation of several of the other types frequently puzzles the expert microscopist. The size of a laryngeal growth will vary from that of a pin's head to that of a mass almost completely blocking up the cavity of the organ. These tumors may likewise be located in any part of the larynx, their favorite site being in the immediate vicinity of the vocal cords. The principal symptoms occasioned by this type of larnygeal disease are: impairment of the voice, either speaking or singing, or both, and interference with respiratory action. At the present advanced state of the science of laryngology no one would think of removing a laryngeal neoplasm other than *per vias naturales*, unless there was eminent danger of strangulation, or the extent of the mass be so great as to prevent the possibility of its extraction *per orem*.

For the performance of this operation several instruments have been devised, the laryngeal forceps of Mackenzie of London, however, taking precedence. Within the past four months I have used a hitherto disregarded instrument, which, with several important alterations, has done good service; but of this more anon. Generally speaking, several sittings are necessary to the complete extirpation of a laryngeal growth, although it will not infrequently happen that a single introduction of the forceps will suffice. Although much has been said, pro and con, regarding the evulsion of laryngeal tumors by means of instruments introduced into the organ itself through the mouth, it has been quite fully established by laryngoscopists that this operation should always be performed when practicable. There need be no bad secondary effects if ordinary precaution be exercised by the operator, and a few simple rules be observed. In the first place, the forceps should not be introduced too frequently at a single sitting; in the second place, too much force should not be used during traction; again, a sufficient interval should be allowed to intervene between the sittings, to insure the subsidence of whatever inflammation may have been occasioned by the laryngeal manipulations; and lastly, the operator must, in every instance, be guided by good judgment and common sense. Subjoined will be found a quartette of interesting cases selected from a number operated upon, both in hospital and private practice.

Case I.—J. M——, a German, aged eighteen, applied for treatment at the Metropolitan Throat Hospital, in September, 1878, complaining of hoarseness and impaired breathing. Upon laryngeal examination, a growth was distinctly seen located on the superior surface of the left vocal cord. The tumor was of the papillomatous variety, and covered nearly the entire body.

In the evulsion of the above mass a pair of Mackenzie's antero-posterior forceps were used, several operations being necessary to its complete extraction, owing not only to the close proximity of the vocal body—the growth requiring to be delicately picked from its surface—but also to the soft nature of the tumor, which allowed only that portion caught in the mouth of the instrument to be removed. The entire operation necessitated some five or six sittings, the mass being completely removed. Two years subsequent to the treatment a laryngeal examination revealed not the slightest trace of its existence. As a result of the operation, voice was completely restored, both as regards singing and speaking, the boy being enabled to resume his connections with a German singing society of which he had been formerly a member.

Case II.—Joseph Y——, aged forty-five, consulted me at the Metropolitan Throat Hospital, in February, 1879, complaining of hoarseness and cough, the latter symptom being of a very distressing nature, and at times spasmodic. Upon laryngoscopic examination, the mouth-mirror plainly revealed a large mass occupying the central portion of the cavity of the larynx, which was attached by a distinct pedicle to the superior surface of the right vocal cord, the remaining portion, the body, being free.

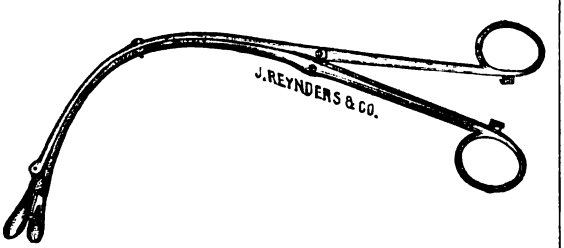
During quiet respiration the neoplasm hung suspended between the vocal cords, extending some little distance below these bodies. When, however, phonation was indulged in, its position was somewhat altered, being forced upward by the adduction or coming together of the vocal bands. In the extraction of this tumor the same instrument was employed as in Case I. a single introduction of the forceps being sufficient for its complete removal. In the performance of the operation advantage was taken of the peculiar movements of the growth during phonation, described above, and, when the instrument was *in situ*, the patient was requested to say Ah! which forced the neoplasm into the jaws of the forceps waiting invitingly open to receive it.

Case III.—Mrs. McM——, a widow, aged fifty, applied for treatment to the Metropolitan Throat Hospital, in March, 1879, complaining of hoarseness, which was of a degree bordering on complete aphonia, and impaired breathing, which was extremely difficult and labored. She had, besides, a very distressing cough. Upon laryngeal inspection three small polypi were discovered attached to the vocal cords, two on the left, and the remaining one on the right body. During adduction these tumors interlocked with one another, which added considerably to the interest of the case. Owing to the extreme weakness of the patient, from the constant interference with respiration, she being unable to walk one-half of a square without halting for rest, I had considerable difficulty in persuading her to undergo an operation; but, after describing the gravity of the condition, my patient finally consented. In the extraction of these tumors the same instrument was used as in the two cases recorded above, a greater number of sittings, however, being required—twelve in all—not only on account of the weakened condition of the patient, but also owing to the extreme sensitiveness of the larynx and neighboring soft

parts. The treatment of the case was pre-eminently satisfactory, not only to myself, but also to the sufferer, the growths being entirely removed, and the difficulties of respiration for the most part overcome, the patient being able to walk a considerable distance without fatigue. The above case is the only one among the number operated upon in which any untoward result followed the introduction of the laryngeal forceps, one of the sittings being productive of a considerable amount of œdematous swelling in the larynx, which caused a great deal of alarm to the patient, but happily the tumefaction was subdued in a few hours by the constant inhalation of benzoin vapor.

CASE IV.—Mr. M——, aged thirty, consulted me at my office, in May, 1881, at the suggestion of his family physician, Dr. Wood. This case, which is by far the most interesting of all, presented the same general symptoms as those already tabulated, viz.: impairment of the voice, obstruction to respiratory action, and cough—the difficulty of breathing being the most prominent. Upon laryngoscopic examination a large mass was plainly seen occupying the left side of the larynx, immediately above the left vocal body, which was removed without any special difficulty, by means of Mackenzie's forceps. Upon making an exploration of the parts, several days subsequent to the above operation, I was greatly surprised to see a second growth subjacent to the cords, and occupying the left side of the windpipe, which neoplasm was not attached to the under-surface of the vocal band, but to the laryngeal wall, at a short distance from the cord.

Immediately resuming operations with the instrument used in the first instance, I endeavored to extract this second tumor; but, after several ineffectual attempts to grasp the growth, I was obliged to abandon this style of forceps, on account of my not being able to introduce it far enough down in the larynx. Upon searching through the various instrument stores of this city, I discovered a French forceps, which, I thought, with several alterations, would answer the requirements of this particular case, and communicating my ideas to J. Reynders & Co., the subjoined instrument was constructed, which served my purpose admirably, every visible portion of the tumor being easily removed.



In favor of the forceps depicted above, several strong points can be advanced:

*First.*—On account of its peculiar mechanical action it can be introduced to a considerable distance below the vocal cords, with extreme ease.

*Second.*—Although much finer in construction than the generality of laryngeal forceps, it is exceedingly powerful.

*Third.*—Its jaws opening only at the extremity, there is less liability of impinging the neighboring structures.

Since the last-mentioned operation I have had occasion to use this instrument in the case of a small polyp, located on the inter-arytenoid membrane, and it acted so satisfactorily that I do not hesitate to recommend it for the evulsion of growths situated above as well as below the glottis.

339 WEST TWENTY-THIRD STREET.

## A CASE OF CEREBRAL HEMORRHAGE RESULTING IN "ALTERNATING" OR "CROSSED" PARALYSIS—EXTRAVASATION OF BLOOD INTO THE PONS VAROLII.

BY TALBOT JONES, M.D.,

ST. PAUL, MINN.

THERE has recently fallen under my observation in this city, a case of cerebral hemorrhage, resulting in hemiplegia, so instructive in the lessons it conveyed as regards localization in brain disease; so unusual in its mode of outset; pursuing such an anomalous course; producing such an infrequent chain of objective symptoms; and, inferentially, occurring in such an unusual situation, or centre of the cerebral mass, that I have determined to place it upon record. Localization of brain lesions has been, during the last decade, largely studied, and there have been positive advances made in the subject which still continues to engross the attention of the medical profession. Our increased knowledge is due to investigations in morbid anatomy and experimental physiology, and largely as a result of clinical observation. The important investigations made by Fritsch and Hitzig in 1870, by electrization of the cerebral hemispheres in the lower animals, gave results of capital importance. These experiments, which at once attracted great attention to the subject, were quickly followed by those of Ferrier, though the latter's were far more comprehensive in their details and valuable in their results.* A score or more of earnest investigators soon began to labor in the same field, and the result of the investigations of Broca, Hughlings Jackson, Schiff, Vulpian, Sanderson, Bouchard, and others, are now well known to the scientific world. In the investigation of cerebral localization, however, it soon became apparent to those making the experiments, that a much larger amount of clinical material than was available, would be needed ere positive deductions could be drawn, or generalization made as to the site of the hemorrhage, from given objective symptoms in the patient.

Indeed, the most serious drawback to the full elucidation of the difficult problem of cerebral localization, in so far as it relates to determining the site of blood extravasation in given portions of the brain, has been due either to an indifference or failure on the part of physicians to report their cases.

It is, of course, highly desirable, when called to a case of apoplexy, to be able at once to determine, with reasonable certainty, that portion of the brain which is the seat of the lesion: whether it be in the sensory or motor track; whether it be cerebral or meningeal; whether or not the extravasation has broken through into the lateral ventricles; or if the effusion be in the corpus striatum, pons Varolii, cerebellum, or medulla. Owing to the advances made during the last decade, in localizing cerebral lesions, much light has been thrown upon what has heretofore been a comparatively obscure subject,

* Ferrier on the Functions of the Brain. 1876.

and we are at the present time enabled to predict, with much more certainty, what particular portion of the nervous mass has suffered from characteristic symptoms which follow the injury of each. Still, much remains to be learnt—clinical observation should be made to replace inferential reasoning. While this is true, it is equally true that there is oftentimes observed, as a result of cerebral apoplexy, certain symptoms, or even groups of symptoms, highly characteristic of this general condition, yet which afford no positive clue to the site of the injury, which is ascertained only by a post-mortem examination. It is not only desirable, but is the duty of observers, to put upon record every case of cerebral hemorrhage occurring in an unusual situation.

It is possible that a recognition of this obligation induced Moxon to record ("Path. Soc. Trans." 1869–70) a case of paralysis of the facial nerve from hemorrhage into the aqueductus Fallopii; and Hughlings Jackson to report a case of blood extravasation into the pons Varolii (*Reports to the London Hospital*, vol. i., 1864).

Numerous other instances could be cited where eminent observers have reported cases of hemorrhage in unusual situations. The following case is given in the hope that it may aid, however so slightly, a diagnosis of cerebral hemorrhage in a location where it indeed rarely occurs.

Mrs. J. W. R——, fifty-nine years of age, a native of England, resided in Illinois, formerly of Pittsburg, was one of the numerous peripatetic dwellers of Minnesota, having come hither to escape her annual plague—hay fever. She moved in the higher walks of life, was gifted and accomplished. Two years ago, while in Alleghany, she experienced, suddenly, some difficulty with her tongue, which disappeared in one week. It was diagnosed paralysis by the attending physician.

About one year subsequently she suffered an attack of apoplexy, followed by unilateral hemiplegia on the left side, from which, however, she partially recovered. About six weeks ago, while visiting in St. Cloud, Minn., she was prostrated by the third attack of apoplexy, followed by a loss of consciousness and right hemiplegia. She was attended by Dr. A. O. Gilman, of that city. The extravasation had evidently occurred high up in the motor zone, since sensation was unimpaired, and there resulted no injury to the cranial nerves. She remained there for several weeks, but the improvement in her paralysis was very slight. Starting homeward, with her husband's assistance, she reached this city on Sunday morning, October 9th, stopping at the Sherman House, where I was called to see her at 5 o'clock P.M. I found the patient with a flushed face, and breathing stertorously. Her pulse was slow and full. Temperature in the axilla, 97° F. There was lateral deviation both of the head and the eyes, both being inclined to the left side—the side of the brain-lesion—the non-paralyzed side.

Her eyes were open, and with an unmeaning stare were kept fixedly upon one spot. They could not be made to follow the movements of the hand, when this was moved laterally before them. The pupils were neither dilated nor contracted, and responded sluggishly to light. The unconciousness was rather profound, as there was no intelligent response when the patient was loudly spoken to, or attempts made to arouse her. There was complete *right* hemiplegia, but strong irritation induced slight reflex movements in the paralyzed limbs. In raising the arm, and allowing it to drop, it fell, at the side of the body, inanimate.

Deglutition, however, could be performed, and liquids were swallowed when placed in the back part of the pharynx. The muscles of the face on the side corresponding with the lesion, and *opposite* the hemiplegic side of the body, were palsied and powerless, and the countenance on that side bore a characteristic vacant look from the absence of all expression. The angle of the mouth was drawn lower, and the paralyzed half of the mouth looked longer than that of the sound side. The muscles affected were those of expression, innervated by the seventh nerve.

The breathing was laborious and noisy, the cheek in each moving expiration being puffed out with a sort of explosive sound.

The patient it seems had been comfortable in the morning, and had partaken of rather a hearty meal at one o'clock P.M. Shortly after she began to gape, and there was observed in her a desire for sleep. An increasing drowsiness was noticed, and the patient glided gradually into unconsciousness, the coma being rather profound. There was an entire absence of a convulsion, of pain in the head, vomiting, nausea, giddiness, weakness of the limbs, or, indeed, any prodromal symptoms.

The difficult problem of diagnosis now presented itself. The coma of alcohol and narcotic poisons were readily excluded. To differentiate from the coma of uræmia: This state was not preceded by a convulsion, and the exceptional instances where this is not the case are very few indeed (Da Costa). But, in addition, there was no history of renal disease; no puffiness of the eyelids nor swollen condition of the ankles. The urine, which was passed in napkins, was not examined for albumen or casts.

Syncope, asphyxia, and cerebral hysteria, after a careful consideration of each, were excluded.

The symptoms observed were similar to those produced by acute softening, obstruction of the cerebral arteries, and the so-called serous apoplexy (œdema of the brain). Rostan tells us that one half of his cases of acute softening occurred suddenly, and the symptoms noted were precisely the same as those produced by clot. Indeed the symptoms following acute softening so closely resemble those of apoplexy, that a differential diagnosis is often impossible. The state of the patient's arteries, however, furnished valuable information with regard to differential diagnosis. As before stated, her pulse was slow, but strong; the arteries were rigid and hard, feeling like a rod of metal under the finger. There evidently existed a condition of wide-spread arterial degeneration. It should be remembered that she had on three previous occasions suffered attacks of paralysis, presumably due to the rupture of minute miliary aneurisms, "for recent researches have rendered it likely that the extravasation of blood is always due to the same immediate cause—to rupture of miliary aneurisms on the minute arteries, which are constantly found to be diseased" (Charcot: *Arch. de Physiol.*, 1868). Arguing this subject of differential diagnosis, J. Hughlings Jackson, after an able process of reasoning remarks: "If the patient have tough arteries, if deep coma has occurred suddenly or quickly, with one-sided symptoms of any kind, it points at least to intra-cranial, if not cerebral hemorrhage, in the vast majority of patients past middle age." These facts, and others that need not be mentioned, were fair presumptive evidence that the causation was not from softening, and the etiology

should be looked for elsewhere. The mode of onset being rather slow, and not of abrupt origin, sufficed to differentiate it from embolism. This opinion was strengthened, and amounted to a positive conviction, when, after a careful cardiac examination, no valvular disease could be detected, nor any history furnished of prior rheumatic endocarditis. (Resonance on percussing the chest was vasiculo-tympanitic in quality, while auscultation revealed sibilant and a few sonorous râles widely distributed.) With regard to the rapid effusion of serum (serous apoplexy) the difficulty of distinction was, if possible, even greater still. However, the previous history of brittle arteries, the age of the patient, the course the case subsequently pursued, together with the absence of certain symptoms which are supposed to denote the effusion of serum, were deemed fairly sufficient to exclude it. The symptoms referred to are pallor of the face, feebleness of the pulse, and an "increased secretion from the mouth and eyes" (Durand Fardel). In comparatively rare cases only does pressure upon the brain result from turgescence of the vessels, or from an effusion of serum (Da Costa).

The etiology of this apoplexy, or hemiplegia, which the latter derivatively signifies, was, however, a far less interesting study than the seat or situation of the lesion. The question arose: Can the seat and extent of the lesion be ascertained by the symptoms? In attempting to answer this question, a knowledge of cerebral localization alone could be relied upon. It need scarcely be said that, in the vast majority of cases of cerebral hemorrhage, the location is either in the optic thalamus or corpus striatum; next in frequency in the gray matter of the convolutions, rarely in the cerebellum, and less frequently of all in the pons Varolii and medulla. The hemorrhage in this case evidently was not meningeal, as the latter rarely gives rise to hemiplegia, and besides there was no rigidity of the muscles of the extremities.

A blood extravasation high up in the motor or sensory zones, as the optic thalamus or corpus striatum, would in this case leave unexplained the facial paralysis on the side opposite the hemiplegia, so the lesion could have its seat in neither of these centres. The lateral ventricles were not invaded, else formidable symptoms of profound coma and tonic alternating with clonic spasms of the muscles, would have developed. Hemorrhage into the crura cerebri, cerebellum, and medulla, give rise to symptoms sufficiently characteristic of each, yet a lesion in neither of these centres produces facial palsy. Gubler, indeed, has reported a case of cerebellar hemorrhage followed by facial paralysis on the side corresponding to the clot, but an immense preponderance of opinion is opposed to this view. It appears paradoxical that this same author should in another paper (*Gaz. Hebdom.*, 1858) make the statement, without qualification, "that hemorrhage into one-half of the pons gives rises to palsy of the extremities of one side and of the face on the other."

Moxon's case,* where facial palsy followed an extravasation into the aqueductus Fallopii, is readily understood when we remember that the aqueductus Fallopii is a groove for the passage of the portio dura nerve.

These cases are the only exceptions I am aware of to that rule, that hemiplegia upon one side and facial paralysis on the other is due to a lesion of the pons Varolii. Upon this question the information gained from a study of morbid anatomy and experimental physiology is in perfect accord with that of clinical observation.

When paralysis of the face occurs on the opposite side to that of the body, it may be inferred that the disease has affected the cranial nerve in a part of its course before decussation has taken place; and pathological observations support this view, unilateral disease of the pons Varolii causing paralysis of the same side of the face as the disease, and the opposite side to the paralysis of the limbs (Foster: "A Text Book of Physiology"). It is probable (Cf. Baleghian: Eckhard's "Beiträge," 1878) that the decussation which begins in the spinal cord, is gradually completed as the impulses pass through the medulla and pons Varolii.

For a full and exhaustive study of the symptoms following disease of the pons Varolii, see Lockhart Clarke's papers ("Phil. Trans.," 1868) and Brown-Séquard's lectures published in the *Lancet*, 1861, vol. ii. Assuming then that my patient's apoplexy was due to cerebral hemorrhage, and that the location of the hemorrhage was in the pons Varolii, was there any means of ascertaining in which one of the different levels in this nervous centre the extravasation occurred? J. Hughlings Jackson, in his able article on cerebral hemorrhage and apoplexy in Reynolds' "System of Medicine," learnedly discusses this very question, and sheds so much light upon the subject, that I believe an affirmative answer to the question possible. This author, in stating a hypothetical case, almost perfectly described my patient's symptoms. He says: 1st. "A lesion in the *lower* part of the pons, on the left side, will catch the fibres of the left facial nerve before its decussation, and will also involve the fibres from the right limbs, which have crossed lower down in the medulla. There is then palsy of the left side of the face on the side of the lesion, and of the arm and leg on the right, the side opposite the lesion." 2d. "A lesion in the *upper* part of the pons (Brown-Séquard) may destroy the fibres of the right facial nerve, which have crossed in the pons, and will also involve the fibres for the right limbs. Here then the facial paralysis will be on the side opposite the lesion, and therefore on the same side as the palsy of the arm and leg." 3d. "Lastly, Brown-Séquard points out that a lesion in the *middle* of the pons will catch the fibres of the left facial nerve *before* its decussation, and those of the right *after* its decussation. Then the face is palsied on both sides from lesion of the left half of the pons, and the arm and leg on the right."

If the foregoing explanation be correct, and there is scarcely room to doubt that it is so, the lesion in my case was located in the lowest level in the pons, and on the left side. A lesion in such a site in the brain must be of rare occurrence indeed; but this is of scarcely more interest than the subsequent clinical history of the case. The coma, the stertorous breathing, the lateral deviation of the head and eyes, and the unilateral paralysis of the face-muscles, which were first observed at five o'clock P.M., showed no signs of improvement six hours later, when the patient was again seen. The forebodings were gloomy, and an unfavorable prognosis given. The following morning found the patient in much the same condition; the pulse was still strong, full, and regular, the coma persistent, and the temperature remained at 97° F. The day following the symptoms were the same, save that the temperature had risen slightly—marking 98° F.

* Op. cit.

Space forbids my giving the daily clinical symptoms in detail, full notes of which I preserve, so it may suffice to say that all the foregoing symptoms remained much the same in kind, not intensified in degree, until the following Thursday noon, when, for a brief period of time, the patient's condition denoted an improvement. Her pulse, in the meantime controlled by cardiac sedatives, was 96° F. Temperature 99⅘° F. She partly aroused from her comatose state, and became semi-conscious; protruded her tongue, which inclined to the left side, when loudly commanded to do so. Her eyes now followed persons moving about in the room, or the hand when placed before them. When asked by her son if she recognized him, she said "Yes," and smiled.

In smiling or speaking, the full extent of the facial palsy was well shown. During these acts, owing to a loss of antagonism of the sound-side muscles, the symptoms of palsy were much exaggerated. The improvement was of but short duration. She soon lapsed into her former condition and remained so until Sunday evening, when a decided change for the worse was noticed. Her pulse was now feeble and intermittent; her breathing, still stertorous in character, became more rapid and shallow, while her temperature registered 101⅘° F. Bourneville has shown that there is, in these cases, a rapid rise in temperature just preceding death, but in this instance I could not confirm his statement, as I was not present at her death, which occurred at 2 A.M. Monday. The length of her illness was seven and one-half days. An autopsy was refused, which, for obvious reasons, I was extremely anxious to make.

I have a natural diffidence in reporting this case, for "when hemorrhage has taken place in the pons, the diagnosis is very difficult" (Da Costa), and the diagnosis made during life, in this instance, could not be verified by a post-mortem examination. By way of justification, however, I may plead that if the opinions formed were correct, it is but right and proper to report it, as a slight means of aiding subsequent observers in their diagnosis of hemorrhage into a very unusual centre in the brain; and if wrong it can be quickly corrected, and the error pointed out by those whom large experience or special study render competent to undertake the task.

By way of summary, it may be said that the features, both interesting and unusual in the case, were these:

*First.*—The location or site of the lesion.

*Second.*—An entire absence of prodromes, save that of drowsiness and gaping. The abruptness of an attack of apoplexy is implied in the name. To that generally accepted opinion, that there are usually some signs of an impending attack, Trousseau excepts cases of hemorrhage into the pons Varolii; but even in cases of hemorrhage into the pons there are, according to Hughlings Jackson, some symptoms before the loss of consciousness. This view, which at present generally obtains, is, however, at variance with that of Rocheaux, who analyzed sixty-three cases of hemorrhage occurring in different centres of the cerebrum, and found prodromes present in only nine.

*Third.*—The very deliberate mode of onset. Yet Abercrombie informs us that these gradual cases are more dangerous than those of abrupt origin, and Hughlings Jackson says "coma from effusion of blood into the pons Varolii will, it is true, come on deliberately, but not so deliberately as opium-poisoning." My own idea is that in this case there was a small extravasation of blood in the left half of the pons, in its lowest level, and that the extravasation occurred slowly.

*Fourth.*—Absence of convulsions of the epileptiform variety, "which, with coincident unconsciousness, usually signifies large hemorrhage, or hemorrhage into the pons or medulla" (Bartholow).

*Fifth.*—The fact that the lateral deviation of the eyes were *toward* the brain lesion, and opposite the hemiplegic side. Bastian ("Paralysis from Brain Disease") says that in a lesion of the pons there is an exception to the rule that the lateral deviation of the eyes, so frequently present in apoplexy, is *toward* the side of the brain affection. I merely note the exception to Bastian's rule in my case, without attempting its explanation, for of the cause I am ignorant.

*Sixth.*—The pupils were not contracted, and it is contracted pupils that most authors describe as one of a chain of symptoms belonging to a lesion of the pons. J. Hughlings Jackson and Wilks (*Guy's Hospital Reports*, 1866) remark, however, that the state of the pupils are of little value as a means of diagnosis. The latter author says: "We cannot connect the condition of the pupils with any definite lesions, for their states are very variable, and liable to be influenced by very slight causes;" and Jackson remarks: "I have not yet seen minute contraction of the pupil on one side from clot in the pons, where there has been coma."

*Seventh.*—But by far the most remarkable feature of the case was the prolonged state of coma. With the exception of a lucid or semi-conscious period, lasting for a few hours only, she remained unconscious continuously for a space of seven and one half days. I have thus far searched literature in vain for a counterpart of the case.

Hemorrhage into the pons or medulla is very fatal—from fifteen minutes to several hours (Bartholow). This is the generally accepted view. I see but one explanation of this, that is to assume that the hemorrhage was slow, and the resultant clot small in size.

---

A Bad Case of Globus.—Dr. Myers, of Patterson, N. J., was recently summoned in great haste, at midnight, to see a woman who was suffering the most excruciating agonies from having swallowed a set of false upper teeth, sixteen in number. Several women were about her, who had been called in to help her. Anodynes were administered to relieve her temporarily. Dr. Myers then closely scrutinized her mouth and throat, but could find no evidence of laceration. Moreover, she could swallow readily. He suggested that the teeth might have been mislaid, but this was indignantly scouted by the attendants, who declared that they had searched the house from top to bottom. A further search under the pillow failed to disclose the missing property, and the case began to look serious, as the poor woman declared that she could not stand it any longer, as she felt the edge of the teeth cutting into the sides of her stomach. Finally, at the suggestion of the doctor, the inside of one of the pillow-cases was examined, and there the teeth were found, perfectly safe and harmless. The patient, who had a moment before been suffering from the laceration of the teeth "against the edges of her stomach," recovered instantly, and the doctor was promptly dismissed.

Dr. F. E. Beckwith, having been elected Professor of Obstetrics and Diseases of Children in the Medical Department of Yale College, has removed to New Haven, Conn.

SERVICE OF D. HAYES AGNEW, M.D.

### CLINICAL REMARKS ON LITHOTOMY IN CHILDREN, AND ITS COMPLICATIONS.

THIS boy is six years of age. He was brought into the house a few days ago suffering from intense vesical irritation; he had frequent micturition, and every few minutes passed water. He had pain especially toward the end of the act, as the bladder became emptied. At this time he would always have the disposition to grasp the prepuce, and pull, to get relief. These symptoms are so characteristic that you will say at once that, in all probability, there is a stone in the bladder. These signs alone, however, will not be sufficient to justify an operation. There are a great many bladder and kidney troubles in which the patient has pain similar to what we find in this case. There may be the same frequency of micturition and pain, and there may be the same disposition to pull at the prepuce. But why does the patient complain of pain at the end of micturition? It is due to the bladder contracting on the stone.

It is quite common for persons suffering from urinary calculus to have occasionally acute attacks of vesical irritation—"fits of stone," as they are sometimes called—after exposure to cold or unusual exercise; as, for instance, riding over rough roads, causing the foreign body to be rolled about in the bladder.

To determine absolutely the presence of stone, a sound should be introduced into the bladder in the same manner as introducing a catheter. Usually, the concretion is felt as soon as the instrument enters the bladder; but if not, the sound should be turned around and moved in different directions. To hear the sound produced by the contact of the instrument with the calculus is more important, in a diagnostic point of view, than simply to feel the stone. By attaching this sounding board to the sound, the clink can be rendered audible over this large room.

In operating for calculus in children, we always employ lithotomy. The mortality after the operation is very small indeed. The size of the urethra of children is not suited for the operation of lithotrity.

The preliminary treatment consists in keeping the patient quiet for a few days, regulating his diet, and seeing that the bowels are freely opened. The rectum should be emptied, by an injection, about two hours before the operation, using for this purpose a little soap and water. The table to be used should be firm and narrow; such a one as may be found in any country kitchen.

Before proceeding to the operation introduce the sound, and satisfy yourself *at the time* that the stone is present; if unsuccessful in detecting the calculus, it is safer to defer the operation. You can all hear the sound produced as the instrument strikes the stone.

There are several methods of performing lithotomy; we have the lateral, bilateral, median, and suprapubic operations. In lateral lithotomy the line of incision is on the left side of the perineum, extending inward and through the prostate gland and the neck of the bladder. In bilateral lithotomy a semilunar incision is made from one ischiorectal space to the other, across the perineum, about three-fourths of an inch in front of the anus. In median lithotomy the incision is made in the middle of the perineum. In the suprapubic method the incision is vertical, and just above the symphysis pubis.

In the lateral operation the incision, beginning three-fourths of an inch in front of the anus, and on the left side of the raphe, is carried downward and outward to a point midway between the anus and tuber ischii, dividing, as it is deepened, the integument, superficial fascia, middle perineal and transverse perineal muscles with its accompanying artery. Farther inward the knife enters the space between the accelerator-urinæ and erector-penis muscles, and divides the deep perineal fascia or triangular ligament with the compressor-urethra muscle, the membranous and prostatic portions of the urethra and the prostate body.

While the incision is being made the finger must press the rectum away from the knife. After opening the bladder the finger is introduced into the viscus and the staff withdrawn. The forceps are now conducted along the finger into the bladder, and the stone delivered.

After the extraction of the calculus we wash out the bladder, so that no *débris* shall be allowed to remain and become the nucleus for another concretion. Looking to the bleeding, we see that the transverse perineal is the only artery cut, and the hemorrhage from this source has entirely stopped.

The subsequent treatment consists in placing the child in bed, keeping him quiet, and giving him nothing but milk for three or four days; the bowels should be kept quiet for at least three or four days, administering, if necessary, two or three drops of laudanum for this purpose. For the first two or three days the water usually escapes freely through the wound. After this, for some period, it will flow through the urethra, owing to an inflammatory swelling closing the cut. Two or three days after that, it resumes the channel made by the knife, continuing to flow in this way until the wound is gradually closed by granulation, and the urine follows its natural channel through the urethra.

It requires, as a rule, from three to four weeks for recovery. In one case a child was permitted to go out of the hospital in nine days. The lad upon whom I operated about a month ago was discharged three weeks after the operation.

There are several accidents that may happen during lithotomy. One of the most common of these is failure to enter the bladder. It is more likely to happen in operating upon children. If the opening into the urethra has not been made sufficiently free, the finger, and sometimes even the forceps, may glide into the recto-vesical space, the fascia of which is quite loose and unresisting. This accident is unfortunate, and quite likely to be followed by infiltration and fatal pelvic inflammation. On the other hand, if you incise the prostate and neck of the bladder too freely, it is possible to miss the prostate altogether, and penetrate the bladder posterior to the prostate body. Children have very small prostates, and the knife must be used with precision. If the stone is of unusual size, and yet not altogether too large, it will be best to enlarge the opening in the prostate; the cut may be made with a blunt-pointed bistoury. I am opposed to tearing, which

some advocate; if, however, the prostate be divided by two incisions through the lateral portions of the gland, so that a triangular flap is produced, the opening will allow of the passage of a very large calculus.

The complication of hemorrhage is not a frequent one. Although the transverse perineal artery is divided at every operation, yet this vessel, in most cases, closes spontaneously, and rarely needs a ligature. The artery of the bulb, however, is necessarily very much exposed. In order to avoid this vessel, after making first a free incision, I work backward rather than anteriorly, being careful not to carry the knife too far forward. The internal pudic has also, on some occasions, been wounded. Unless the knife is greatly lateralized there is no danger of wounding this vessel. There may also be a free bleeding from the neck of the bladder, the source of which is the prostatic plexus of veins, which you know are large and tortuous. When a case of this kind occurs how are you to manage it? You do not expect to tie the vessels. Introduce a soft catheter through the incision into the bladder, and pack the wound firmly with a long strip of lint. This should be removed in from twenty-four to thirty-six hours. You may also control all hemorrhage by introducing a finger into the rectum, and pressing the bowel up against the pubic arch. But how long are you to keep it there? Perhaps by means of assistance you might be able to keep it up for many hours. This is a sovereign means of arresting hemorrhage, and was first practised by Dr. Kerr, a distinguished operater in China. He substituted pressure with the finger by packing the bowel with lint.

There is no excuse for a patient dying of hemorrhage after this operation when we have such ample means for its control. It may be necessary in some instances to ligate the internal pudic; this ligature is a difficult one, perhaps one of the most difficult in surgery. The vessel is large, and from it the artery of the bulb is given off. Here is an instrument consisting of a forceps and needle, devised by Physick for tying this vessel, but it is not at all suited to this purpose, nor have I ever seen any report of the artery being tied by means of it. The only instrument well adapted for this ligation is an instrument devised by Dr. Horner, and called Horner's awl. It consists of a strong curved needle like a shoemaker's awl, with a shoulder instead of an eye, near its extremity, and a strong handle; over the shoulder is looped the thread or ligature. After the needle, armed with the ligature, is passed underneath the vessel and emerges on the other side, the loop is disengaged from the shoulder of the instrument, which is then withdrawn and the thread tied. Ligation of this artery commands, of course, any bleeding from the artery of the bulb; it is impossible to avoid taking up with the vessel, the vein, and sometimes, also, the nerve. I know of no way in which you can prevent it. Twice I have tied the artery by this instrument without any difficulty.

NOTE.—The following week Prof. Agnew operated again before the class for vesical calculus, using the same method as in the previous case. The subject was twenty years of age, and had had symptoms of stone from childhood. Just before the incision was to have been made, the sphincter-ani became so completely relaxed from etherization that every expiration caused the rectum to be distinctly seen, and by the entrance of air to become distended. The operator waited until these effects of etherization disappeared. Prof. Agnew said that this was a complication, which he had never heard spoken of in connection with the operation, but one which it was very important to recognize.

November 5th.—The three cases of lithotomy alluded to above have progressed favorably without the slightest untoward symptom.

## Progress of Medical Science.

THE WEIGHT OF THE HUMAN BRAIN.—While house-physician to the municipal infirmary and hospital of Vienna, Pfleger made an interesting series of observations on the weight of the adult human brain and its component parts, studying also the relative capacity of the cranial cavity, both in sane and insane individuals, with reference to sex and the size of the body. The more important deductions as published in the *Wiener med. Blätter*, No. 27, 1881, may be given as follows: Between the ages of twenty and sixty years there is no variation of any consequence in the proportion which exists between the weight of the brain and the capacity of the corresponding cranium. The former shows a perceptible decrease between the ages of sixty and seventy, which becomes marked after this age. This is equally true of both sexes. The absolute weight of the brain increases, in general, proportionately with the length of the body and that of the trunk. An exception to this rule is found, however, in persons of very small stature; these have usually a brain heavier than individuals who are from ten to fifteen centimetres taller. The relative weight of the brain and its various parts diminishes with increase in the size of the body; this is particularly true of the cerebellum and cerebrum, less so of the brain as a whole, and of the cortex. The absolute increase in weight, which is associated with increasing size of the body, affects the different parts of the brain differently, only that of the cortex seeming to be constant. The cavity of the cranium in females is smaller, in comparison with the length of the body and of the trunk, than it is in males. The female brain, at the same time that it is absolutely lighter on an average than that of the male, is also lighter in comparison with the length of the body and that of the trunk. On comparing corresponding parts of the brain in the two sexes with one another, we find the weight of the cerebral cortex greater in the male than in the female, the same being true in a less degree of the cerebellum. The cortex is therefore both absolutely and relatively heavier in the male than in the female, while the cerebellum and also the ganglia are relatively heavier in the female.

The female brain, taken as a whole, is perhaps heavier, on an average, as compared with the capacity of the cranium; yet, even in this case, the weight of the cortex, as compared with the capacity of the cranium, is less in the female than in the male, while the opposite is true of the cerebellum and cerebrum, so that the above-mentioned overweight depends probably upon the relative preponderance of the cerebellum and cerebrum. In persons who have died of such acute diseases as produce the least atrophy of the brain, the difference in weight in the brains of the two sexes is the most marked, amounting to as much as fourteen per cent.

In persons, both sane and insane, who have died of chronic diseases, this difference in weight is less conspicuous (about ten per cent. in the sane and eight per cent. in the insane). The brains of insane males

taken as a whole, and also in their individual parts, suffer a greater loss in weight than those of females affected in the same way, this being true even when we leave out of consideration cases of paralysis, that prevail so much more extensively among men than women.—*Allgemeine med. Central-Zeitung*, July 13, 1881.

EMPHYSEMA OF THE EYELIDS AND OF THE ORBIT.—Dr. Baudry, of Lille, reaches the following conclusions (*Recueil d'Ophthalmologie*, August, 1881) concerning orbito-palpebral emphysema. The term spontaneous emphysema should be applied only to those rare cases in which the air in the nasal fossæ passes spontaneously into the areolæ of the orbito-palpebral cellular tissue, no effort at clearing the nose having been made. Emphysema in this location, which occurs after an effort at clearing the nose, or after sneezing, is the result, in most cases, of a fracture of one of the bones in the internal orbital wall, which permits the direct passage of air from the nasal fossæ into the cellular tissue of the eyelids and of the orbit. The emphysema will be limited to either the lids or the orbit, or may occupy both localities, according to the seat and extent of the fracture and to the varying pressure of the expired air. Under exceptional circumstances, the so-called spontaneous emphysema results from complete rupture of the lachrymo-nasal duct, produced by surgical traumatism. In this case osseous lesions may or may not be present. In still rarer cases the emphysema is attendant upon defective development of the parts in question.

VOLUMINOUS DERMOID CYST OF THE ABDOMEN.—Drs. Sewell and Miller report a case of voluminous cyst filled with solid matter, and occupying almost the whole of the abdomen. Upon post-mortem examination the growth was found to be so intimately united to the rectum and bladder that these organs seemed to form an integral part of its walls. Recent and old adhesions, due to peritonitis, united the cyst to various portions of the intestines. The other viscera were normal. Removed from the abdominal cavity, the cyst presented the shape of a flattened pear. The small extremity of the growth was situated between the bladder and the rectum. The dimensions of the cyst were as follows: length, 13 inches; width, 10 inches above and 4½ below; thickness, from 4 to 8 inches. Examined under water, small hairs were seen projecting across the opening of the cyst. The contents of the growth had a rancid odor, the aspect of a mixture of fat and hair, and the consistency of soap. At one extremity of the cyst the walls closely resembled the lower layers of the chorion of the skin; they contained glandular elements and capillary networks of blood-vessels and lymphatics. This resemblance was confirmed by microscopical examination, which revealed the presence of an epidermis and various layers of the derma with hair-follicles, of which some contained hair, a large number of sebaceous, but no sudoriparous glands. Chemical analysis showed the growth to be composed of 99.75 per cent. of fat and fatty acids. This is a very remarkable and rare specimen of a cyst developed in the abdomen of a man, and is probably unique in regard to its volume. Dr. Wilkes mentions an analogous case of dermoid cyst similarly located, occurring in a man aged twenty-one. Dr. Curling had occasion to treat this patient later, removing from the bladder a soft, phosphatic calculus, the centre of which was composed of small black hairs. Lebert reports ten observations of non-ovarian cysts found in deep parts of the body, and several cases are also alluded to by Blackman.—*Archives Générales de Médecine*, July, 1881; *Medico-Chirurgical Transactions*, Second Series, vol. xlv.

TREATMENT OF PLEURITIC EFFUSION.—From a discussion between Prof. Concato and Drs. Brambilla, Galignani, and Albertazzi, on the comparative merits of the induced current applied to the side of the effusions (Brambilla), and mechanical compression exercised upon the sound side (Concato), the happy conclusion may be drawn that both procedures have been attended with good results, contrary to the assertions of Ghinozzi, Orsi, Ballotta, and others.—*Recoglitore Medico*, July, 1881.

CASE OF SPONTANEOUS OSTEOMYELITIS—TREPHINING—RECOVERY WITH ANCHYLOSIS.—In the *St. Louis Clinical Record* of July, 1881, Dr. Bauer reports a case of spontaneous osteomyelitis seen in consultation with Dr. Briggs in May, 1880. The patient was a foreman in a smelting establishment, and without strumous or syphilitic history. Sudden exposure to cold after over-heating preceded the manifestations of the disease. After sustaining various plans of treatment, the man finally came under the care of Dr. Briggs in a condition of extreme prostration. Through proper attention to domestic hygiene and the comfort of the patient, combined with a rational general treatment, the case progressed favorably. With a view to relieve the still existing intraosseous pressure, and to hasten convalescence, Dr. Bauer advised trephining the affected femur, to which the attending physician and the patient consented. The operation was accordingly performed under anæsthesia by ether. One disc was removed about three inches above the external condyle of the femur, and an outlet thus established from the medullary cavity. The cortical substance of the bone proved to be of greater density and thickness than usual. Sero-plastic material exuded from this cavity, and the flow continued for several days. There was no reaction, and no untoward symptom following the operation. The patient stated that his pain was perceptibly lessened, and very soon the limb could be used without the customary aggravation. The wound closed by granulation. Ten days after the man was again at work, troubled only by anchylosis. According to Dr. Bauer, when the intraosseous pressure is at its height, which point it had already passed in this case, amelioration is immediate and much more marked.

TREATMENT OF CUTANEO-VENOUS ERECTILE TUMORS BY VACCINATION.—M. Paul's new procedure consists in covering the tumor with a layer of virus, and with the cutting needle tracing through the liquid superficial incisions; the latter subsequently become cicatricial lines opposing the extension of the tumor and the rupture of the vessels. At the situation of the erectile tumor, the layer of epidermis is extremely thin, consequently the incisions must be made very superficially and with great caution. To cut entirely through the skin would cause troublesome hemorrhage, and imperil the success of the inoculation. The exudation of a sanguinolent serosity is sufficient indication that the vessels are open, and absorption is possible. When the subcutaneous veins are excessively developed, thermo-cautery may subsequently be used to supplement vaccination. Dr. Paul also employs this procedure in ordinary vaccinations as superior to the methods

of introduction of virus by means of the lancet or needle; in the former instance, the operator may fail to introduce the virus at all; in the latter, the instrument may penetrate the subcutaneous cellular tissue and cause phlegmonous erysipelas. M. Paul has successfully treated four cases of erectile tumor by his procedure. M. Blot first scarifies and then covers the tumor with virus, but M. Paul contends that this gives rise to large and irregular pustules. —*Bull. de l'Acad. de Méd.*, 2me série, tome x., 1881.

On the Hypodermic Administration of Mercurials in Syphilis.—Guided by the counsels of Lewin in Berlin, Pick in Prague, and Sigmund in Vienna, Dr. Streitz has conducted a long series of experiments on the subcutaneous use of mercurials in syphilis, at the military hospital in Brussels. The results of his studies are published in *Les Archives Médicales Belges*, July, 1881.

The most simple mercurial solution for hypodermic use was suggested by Lewin at Berlin. It is the following:

| | |
|---|---|
| ℞. Hydrarg. bichloridi..... | 40 ctgr. (6 gr.). |
| Sodii chloridi ..... | 5 grm. (75 gr.). |
| Aq. destill..... | 40 grm. (℥ x.). |
| Morph. chlorhydrat..... | 20 ctgr. (3 gr.). |

Calomel is not adapted to hypodermic use. The cyanide of mercury may be employed in doses of from one to five milligrammes. The albuminate and the peptonate of mercury, originally prepared by Bamberger, of Vienna, are the safest solutions of all, never producing abscesses or other lesions. The peptonate of mercury is prepared by the following process: (1) 1 grm. (15 gr.) is dissolved in 50 c.c. of distilled water and filtered; (2) 1 grm. (15 gr.) of sublimate is dissolved in 20 grm. (℥ 5) of water, and the solutions mixed; a precipitate is formed, which is redissolved in 15 grm. (℥ 3¾) of a twenty per cent. solution of chloride of sodium. The solution now measures 85 c.c. Enough distilled water is added to make 100 c.c. The solution is allowed to stand one or two days, and is then filtered. Each gramme of the solution contains 1 ctgr. of the peptonate.

Iodo-pepton is a preparation suggested by Pick, of Prague, in which the iodide of potassium replaces the chloride of sodium in Bamberger's solution, above referred to. The combined effect of the iodide and the mercurial are obtained from this preparation, which has given great satisfaction. Dr. Streitz divided his observations into different groups, with a view to ascertaining certain facts. 1st. The patients of this group had reached different stages of syphilis. The object was, in this instance, to discover the solutions possessing the greatest number of advantages, and the places best adapted to injections, and the proper dosage. The solutions selected were those given above. Since they cause the least pain, one-half or two-thirds of a Pravaz's syringeful should be injected into the deep cellular tissue. 2d. This group includes only patients treated at the beginning of the disease, after the chancre had disappeared. In all these patients the cutaneous symptoms were observed, but were not well marked. The eruptions were discrete, being in some cases hard to detect, and rapidly disappeared. 3d. In this group treatment was not instituted until after the appearance of the eruption. The symptoms disappeared quite as promptly and even more rapidly than when other methods of mercurial treatment were employed. Six months after the injections were given only one case among all those treated had experienced a relapse, which showed itself as a papular syphilide, although, as a rule, only fifteen or twenty centigrammes of the sublimates had been given, divided among thirty or forty injections.

The advantages of this method of treatment, as stated by the author, are: the precision in the dosage; the harmlessness of the injections, and the integrity of the digestive organs which they insure; no deception can be practised; mercurial stomatitis is avoided; no abscesses need result; the cure is rapid.

The author makes the following claims for the treatment: secondary symptoms, in patients who had not been treated until the development of the symptoms, disappeared much more rapidly than when treated by other methods; the average period of duration for the papular syphilides was two weeks.

Although injections given early—so soon as chancre was certainly diagnosticated—did not prevent secondary symptoms, the latter were but slightly marked. The injections were particularly efficacious in subduing glandular enlargements at all stages of the disease.

Spontaneous Fractures due to Syphilis.—An interesting case, illustrative of the relations existing between syphilis and spontaneous fractures, is reported by Prof. Amicis, of Naples (*Il Movimento Medico-chirurgico*, fasc. 8, 1880).

P. G——, forty-nine years of age, had a chancre and buboes at the age of eighteen years. Later he had ulcerations on the penis, the nature of which was not determined; in 1875 painful tumors upon the sternum and ribs. He received no constitutional treatment at this time. In 1877 he began to experience pains in the peripheral extremity of the left humerus, which were slight early in the day, but became excruciating toward evening. A mixed treatment relieved them to a certain extent. Two months later, while pulling, with considerable force, upon the strap of a tight shoe he was putting on, he experienced an acute pain in his left arm, which suddenly became the seat of abnormal mobility. At the hospital a fracture of the humerus was recognized and treated for thirty days with an immovable apparatus, at the end of which time union had occurred. Two months later the patient again experienced paroxysmal pains in the forearm, shoulders, and lower extremities. He re-entered the hospital, and, soon afterward, fractured his clavicle while in the act of rising from his bed. Appropriate dressings were applied and kept in position from December 4th until February 6th; but union was still incomplete at the latter date. The patient received the mixed treatment during this time. Complete union had occurred on May 3, 1879.

The history shows that the fracture occurred, as the result of slight muscular action, at a point in the bone weakened by a specific lesion. The probable course of the disease had been as follows: the compact osseous tissue of the diaphysis had become inflamed and disorganized. Caseous degeneration had followed, and finally a cicatrix had been formed: in other words, the bone had been the seat of osteomyelitis or osteo-periostitis, terminating in cicatrization. Virchow has, however, shown that the osseous cicatrix resulting from the healing of syphilitic osteitis is characterized by defective formation at the centre of the newly formed bone, and hyperostosis at the periphery. The cicatrix is, moreover, in part composed of fibrous tissue, and the fragility of the bones at such points is easily comprehensible. Fe-

cent gummata or fibro-osseous cicatrices following them are, therefore, the pathological changes in the bones, predisposing to spontaneous fracture. It is further possible that syphilis causes a reduction in the vitality of the entire osseous system, thus rendering it more vulnerable. This point has not been definitely settled, nor has the relative frequency of spontaneous fractures in syphilitic subjects been ascertained.—*Annales de Dermatologie et de Syphilographie*, July 25, 1881.

Results Obtained by Incomplete Removal of Ovarian Cysts.—M. Terrier (*Revue de Chirurgie*, August 10, 1881) bases the following conclusions regarding the results of partial ablation of ovarian tumors upon the analyses of several cases, and an exhaustive consideration of the literature of the subject.

*First.*—Incomplete operations, consisting in the evacuation of the cyst, the securing of the cyst-walls to the abdominal wound by means of sutures, and in drainage, furnish results which differ widely according to the nature of the cystic tumor.

*Second.*—When the cyst is unilocular, as are serous cysts of the broad ligament and dermoid cysts, the result may be excellent, and the cyst-cavity is finally completely obliterated.

*Third.*—The same results are obtained in certain varieties of multilocular cysts.

*Fourth.*—When, however, a multilocular cyst presents parietal vegetations, the results are very poor: the tumors constantly recur; the abdominal fistula continues open for an indefinite period; and finally, suppuration exposes the patient to septicæmia and exhaustion.

*Fifth.*—Whether the cyst be unilocular or multilocular, there is always a possibility that a pre-existing ovarian tumor, so insignificant as to have escaped observation at the time of the operation, may subsequently be fully developed.

Renal Lesions in Pregnant Women.—Mayor, in a recent publication, has classified the various renal alterations which may occur in pregnant women. Upon this point there is, at present, a great confusion of opinion. Albuminuria of pregnancy is considered by some as due to purely mechanical causes, the uterus in its development compressing the arteries above the kidney, or the renal veins; according to other writers, albuminuria is the result of blood-changes, while others still regard it as a *serumuria*. From his own researches, Mayor is inclined to admit the constant existence of a nephritis, although he does not, categorically, assert it. "All that we can affirm," he writes, "is that on the one hand, in every case of eclampsia, we have observed manifest lesions of the kidneys existed, and on the other the lesions of the secretory cellules of the kidney we have met with in pregnant women are those which Cornil has described as occurring at various periods in the course of parenchymatous nephritis."

In puerperal nephritis, the changes are: first, a period of congestion; this is followed by a second period of *inflammatory anæmia*, during which the formation of casts and the dilatation of tubules take place. The lesions described are characteristic of a nephritis, and do not pertain to the pathological process known as degeneration.

This parenchymatous nephritis is allied to nephritis *a frigore*, and has no relation with the secondary nephritis of febrile affections and acute diseases, or with that form occurring with certain varieties of intoxication. Chemical reaction of the albumen passed was thought to present another argument in favor of the similarity existing between puerperal nephritis and nephritis *a frigore*.

Mayor cites a case which demonstrates that lesions of the kidney predispose women affected with uterine diseases to grave accidents, just as renal trouble exerts a baneful influence in traumatism.

Albuminuria, however, may be absent during pregnancy, and may appear at the time of development of some febrile affection. We cannot look upon the nephritis of pregnancy as a constant precursor of puerperal phenomena and puerperal albuminuria.

Nephritis of pregnancy, as well as the puerperal form, usually yields to treatment. During puerperal fever, changes in the kidney of various characters, are met with; some of these changes begin during pregnancy, others belong properly to the puerperal state. The latter may occur under two different forms, either as parenchymatous changes, or as interstitial suppurative nephritis. This suppurative nephritis is probably similar to that observed in surgery, in pyæmia resulting from affection of one or the other part of the urinary tract (surgical kidney). The parenchymatous changes, in their elementary lesions, resemble those met with in parenchymatous nephritis *a frigore*, and merits the name of puerperal nephritis. This form of parenchymatous nephritis gives rise to but one well-marked symptom—albuminuria. In its anatomical character and its clinical aspect it differs from the renal changes of typhoid fever, and resembles nephritis *a frigore*.—*Revue Méd. de la Suisse Rom.*, and *Il Mov. Med-chir.*, June, 1881.

Laparotomy in Intestinal Occlusion, due to Constricting Bands.—Dr. Claudat publishes one case, and Dr. Boeckel two cases, of laparotomy for strangulation of the intestine by constricting bands (*Revue de Chirurgie*, August 10, 1881). Each observer draws conclusions from his experience in these cases. Dr. Claudat's case terminated fatally. The author regards this result as due to delay in resorting to the operation, and his failure to divide one bridle which constricted the intestine, although he had severed two occluding bands. Dr. C., therefore, insists upon a prompt and early resort to surgical measures for the relief of the strangulated intestine, as soon as the diagnosis can be definitely made and the ordinary medical methods of relief have failed. He regards it as probable, and, indeed, almost certain, that the difficulties attending the operation and the chances of failure in it are in direct proportion to the time which elapses, after the strangulation, before an operation is undertaken. To avoid the error of leaving some constricting band undivided, Dr. C. advises the surgeon to follow the course of the small intestine from the cæcum upward, relieving all constrictions until a coil of healthy bowel is reached, according to the method proposed by M. Duplay. He also recalls the fact that the bowel will be empty below the principal obstruction.

Dr. Boeckel's two cases recovered, although the operations were performed on the sixth and thirteenth day, respectively after the strangulation. From this fact he concludes that there are cases in which the grave symptoms of strangulation are developed at a very late date, in which even tardy operative interference may be successful. Peyat and Petet collected, according to Dr. B., forty-nine cases of laparotomy similar to those just referred to, in which only seven escaped death. This alarming mortality Dr. B. refers to unjustifiable procrastination on the part of the various operators.

# THE MEDICAL RECORD:

## A Weekly Journal of Medicine and Surgery

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, December 17, 1881.

## HOSPITAL SATURDAY AND SUNDAY.

THE approaching anniversary of Hospital Saturday and Sunday, which commences one week from to-day, affords an opportunity for appealing to the public for aid to the large number of sick poor who fill the beds of our charitable institutions. Over ten thousand of these patients were cared for during the past year, and the number is increasing from year to year. For such medical men as are acquainted with hospital work, it is not difficult to answer the question what would become of these needy sufferers if free board, free lodging, and free medical service were not constantly obtainable for them. And the public are beginning to appreciate the situation. Although the present plan of making collections for our hospitals is but two years old, it has received such hearty and substantial indorsements from every quarter that we can speak of it as being quite firmly established in popular favor, and that it is likely to become more so as its real objects are made known. To the latter end the Hospital Committee are using every endeavor, and are systematizing the collection of funds in such a manner as to leave nothing to be desired in the way of insuring the proportionate increase of subscriptions. As practical results of the work of the committee, it may be stated that, during 1879, the first year of the collection, the amount realized was scarcely twenty-six thousand dollars, while that for 1880 was over forty-four thousand. If the sums collected during the present year advance in the same ratio, the period will not long be delayed when the full measure of aid will be meted out to the hospitals by a generous public. In London, with methods of collection which do not compare with ours either in extent or thoroughness, the annual amount collected averages one hundred thousand dollars.

As is well known, gifts for special hospitals may be so designated by the donors, but it is desirable that as much money as possible should be contributed to the general fund, which is divided by the committee in proportion to the number of days of treatment given to free patients by each of the institutions on the list. The latter arrangement admits of no possible partiality, and insures a just distribution of funds in accordance with the actual work done for the poor. The public are consequently assured that their money is thus calculated to do its utmost amount of good in the very quarters where it is most needed and best used.

In looking over the report of last year, it is somewhat surprising to learn the actual amount of work done by the larger hospitals in this city, and to know how much more is needed by pecuniary aid to enable them to do their full measure of charity, and properly discharge their responsibilities toward the helpless sufferers that throng their wards. But with the popularizing of the collection movement, the scarcity of funds with some of these worthy institutions may be, it is hoped, entirely overcome, and New York enabled to care for its sick poor, not only in the most effectual, but in the most economical way.

The managers of the hospitals guarantee the most available medical and surgical skill to the sick poor under their care, and the public should not allow such good intentions to languish for want of pecuniary aid. It has been shown that the average daily cost of a free patient is one dollar and fifteen cents per day, certainly an exceedingly small outlay in proportion to the benefits received. The latter may be briefly summarized under the following heads—lodging, board, nursing, and medical attendance, and the advantages of all the attachments of a large and well-appointed institution.

Even in an economical point of view, the scheme of hospital contributions should appeal to all who are generously disposed; and should, as it doubtless will, tend to popularize this noble system of charity. With the latter end in view, it is proposed to extend the working of the hospital committee to several auxiliary committees representing different business interests, thus forming a co-operative association for hospital subscription and for hospital benefits. Accordingly the committee, with the proper encouragement, will feel warranted in guaranteeing hospital treatment to any member of these organizations at the rate of one dollar per day of the amount subscribed. Thus would be formed an hospital provident association for the poor mechanic and laborer which would insure help for him in his direst need, at the same time preventing him from becoming a pauper. Not only this, but many of the abuses of medical charity would thereby be counteracted, and the proper discrimination of worthy objects be left to a competent and responsible committee. Of course, a great deal of detail

work would be required to perfect a good working plan, but the proper foundations are being laid, and the prospects are reasonably clear toward success. Certainly, the scheme would have the sympathy of a profession which knows most of the needs of the hospitals on one side and the sick poor man on the other. In any event, it will give its cordial support to every endeavor on the part of the hospital committee to raise funds and to encourage any movement to such an end.

---

FURTHER TESTIMONY IN THE GUITEAU CASE.

THE expert testimony for the defence was, it is presumed, closed finally on the 13th. We are obliged to repeat our regrets that it was so comparatively meagre, and that it threw so little additional light upon the question at issue. Two witnesses who were questioned at greatest length were young gentlemen of good scientific abilities, but with less experience and discretion than most of their compeers. The hypothetical question, as we have mentioned before, was very poorly conceived, and it is surprising that any of the experts were contented to answer it.

The evidence of the last witness for the defence, Dr. Spitzka, excited much attention on account of its length, as well as the positiveness of the views expressed. This witness dwelt strongly upon the physical characteristics of Guiteau. The cranial asymmetry, the deficient innervation of one side of the face, and the general expression and manner were thought to argue strongly against the man's mental soundness. Besides this, a belief in an insane hereditary influence added to the witness' confidence in his opinion. Dr. Spitzka was some time ago an advocate of the view that the prisoner was suffering from partial intellectual insanity. His opinion seems to have been somewhat modified now, judging by the evidence recently given. Guiteau's mental condition is there characterized as one in which there is a tendency to delusive opinions and the creation of morbid projects, some imbecility of judgment, and a congenital moral imbecility. The belief that Guiteau was born a moral imbecile, or through disease of the brain became so, was emphasized.

There is not much to be said to all this. We shall be told by other experts that the hereditary influence is doubtful, since Guiteau's insane cousins, one or both, developed insanity through outside influences—it was not in their blood; that Guiteau's father, if insane at all, became so long after Guiteau's birth; that the prisoner's face indicates moral depravity quite as strongly as insanity, and that inferences regarding insanity drawn from the shape of the head are most uncertain; that a prison will show many more mal-formed heads than a lunatic asylum.

It cannot be affirmed that a tendency to delusive opinions, which means, according to the witness, an inability to interpret rightly the affairs, especially the more complex affairs of life, indicates more than perverseness or eccentricity. The same may be said of "a tendency to create morbid projects"—an expression that may mean a great deal or very little.

If, now, we are reduced to the question whether Guiteau's moral depravity is inborn, is the result of disease, or is a consequence of self-indulgence, or whether it comes from a combination of all these factors, we come to a very delicate question. Society must have the benefit of any doubts.

It is difficult to feel great sympathy for a witness who is often so inconsiderately aggressive as Dr. Spitzka. Yet every fair-minded man will share in the feeling of contempt for the mean attempts made by the prosecution to hurt the private character of the witness. And this, notwithstanding the surprising statement of this same gentleman, that whoever took a different ground from himself was either incompetent or dishonest. It is not prudent, at least, for any man, however learned he may claim to be, to say that the ultimate truths of science are locked up in his bosom.

The evidence for the prosecution has, at date of writing, furnished at least one most important fact. It is that Guiteau, some years ago, threatened, that for the sake of the notoriety, he would do some such act as he has already done.

The defence attempted to show that Guiteau was naturally a mild and gentle creature. One of its experts, however, declares him a moral monstrosity. The prosecution has brought a good deal of evidence to support the latter view.

---

FIRES IN THEATRES.

IT is impossible to read the accounts of the recent burning of the Ring Theatre at Vienna, without being impressed with the criminal negligence which caused it. Almost everything was wanting in the construction of the building and its surroundings to secure safety in case of fire. The extra exits provided by law were not only inaccessible, but were locked; the ordinary passages were tortuous, and the stairs narrow; the doors opened into the auditorium and galleries; the fire-alarm was out of order, and consequently could not be worked; the iron safety-curtain was not lowered, neither was any warning of the fire given the audience in time to have allowed the majority present to escape; the firemen of the stage were absent; the gas was turned off by an irresponsible person; the oil lamps were neglected; the large iron door at the back of the stage was open; and no one in authority made any attempt to avert a panic. The sins of omission and commission are strangely combined to

prove how easy it is, by the neglect of necessary details of management, to bring about one of the most dreadful disasters known to history. But probably the most useful thing that will grow out of the terrible experiences in Vienna is an extra precaution against fire by theatre-managers. Already steps to such an end are being taken—fortunately not too late—in this and other cities; but, in the course of events, the law of accidents will spring the balance on the wrong side again, and history will repeat itself with a startling surety. Of course all such lessons teach us the value of vigilance and good management; but, after all, is this not an old enough story, except in the face of dire calamity, to lose its general interest? The people who go to places of amusement will, by-and-by, lose confidence in the desire or ability of the managers to protect them, and will be forced either to stay away altogether or look about them for means to help themselves. A very efficient aid in the latter direction would be a diagram, on each hand-bill, of the plan of the building, with the relative positions of all the means of exit. Generally, it is too late to give this desirable information when a fire occurs. But, above all, does it seem to be necessary to enforce such discipline, in all parts of the theatre, as will prevent an otherwise inevitable stampede for the stairs and doors, and each management should be compelled to maintain its own police for that purpose.

---

### AN ALLEGED POISON IN CANNED MEATS.

No country does so large a business in canned meats, fish, vegetables, and fruit of all kinds as does the United States. For example, there were canned for home and foreign use forty-eight million pounds of salmon alone during the past year, and this represents only what is done in the States on the Pacific coast. We are not aware of any definite statistics regarding the amount of goods canned in other portions of the country, but it is a well-known fact that they form an important part of the stock in every grocer's store, and that enormous quantities are exported to England and other European countries.

It is for this reason that certain facts recently published by Mr. Otto Hehner, R.I.C., in the *Lancet*, are of particular interest to Americans. Mr. Hehner, who is an analytical chemist of high standing, states that he has made a series of investigations into the composition of these canned goods.

The gastric disturbances known to follow at times the use of food that has been "tinned," have been generally assigned to the small amount of lead in the solder with which the cans are closed. Although in rare instances this may be really the case, Mr. Hehner believes that the real danger lies in the poisonous action of certain compounds derived from the tin itself. He has tested the contents of tin cans containing vegetables, meats of all kinds, fish, lobsters, and fruits. All of the samples examined contained more or less of tin. In many the amount was so large that abundant reactions could be obtained from two or three grammes of the vegetable substances, whilst of the animal foods, one of the soups contained thirty-five milligrammes (six grains), one of the condensed milks eight milligrammes, and the oysters forty-five milligrammes of tin to the pound.

Tin, according to the authority quoted, is far more readily attacked by food-matters than is commonly supposed, and is to be found in comparatively large amounts in an overwhelming majority of canned goods, irrespective of the nature of the same. Acid fruits, such as peaches and cherries, readily attack the tin, while meats and vegetables act upon it to a less extent.

Having shown the almost uniform existence of tin in canned goods, Mr. Hehner next discusses the question whether this tin is poisonous. Several experiments were made upon guinea-pigs with stannous hydrate and stannic hydrate. It was found that a little over ten grains of the *stannous* hydrate would produce death in a guinea-pig, with symptoms of irritant poisoning. The stannic hydrate, however, seemed to be innocuous.

The conclusions are that the canned foods would be more likely to cause the production of stannous than stannic hydrate. Consequently, it must be supposed that in most cans there is more or less of an irritant poison.

Mr. Hehner is somewhat indefinite in his statements regarding exactly what is the form of tin oftenest found in the cans. His experiments made to test the character of the tin salts are also extremely meagre and insufficient. In regard to the one fact, however, that tin does exist in the foods preserved in tin cans, there seems to be no doubt. And he has brought enough evidence as to the alleged poisonous effect of this metal to make the matter one deserving further careful investigation.

---

### PRE-NATAL CULTURE.

Science can be very easily made ridiculous. This was abundantly proved, recently, by the proceedings of a body of "reformers" who convened under the name of the "American Institute of Heredity," in this city. The alleged objects of this institution were certainly very praiseworthy. They were to urge the necessity of only those people marrying who would have healthy and moral children. It might indeed have called itself an institution for the creation of perfect husbands and model mothers, except that the necessity of there being any conjugal relation did not seem to be strongly felt. One of the speakers thought that only those who had passed a physical examination before a State

physician ought to marry. It was not so much love, as the length of the conjugate diameter, that should determine matrimonial alliances. Indeed, the growth of "that unsentimental lust called love" was not to be encouraged.

The urgent need of pre-natal education was oppressively felt by all. "Generation before regeneration" was apparently the mystic motto adopted, it being especially good for a motto since it is equally significant whether read backward or forward. Exactly what the pre-natal culture should be was by no means satisfactorily brought out. To be sure, one lady who had had a pre-natal education herself, and knew all about it, did give some definite hints. In her belief, all that is necessary is that the mother should will, with the same regularity that she performs her other functions, that the unborn child should be an artist, a musician, a poet, or a burglar. The result, said the speaker, as proved in her experience, would be just what was desired. We might believe that there was something in this, if it were not for the uncertainties of sex. For the mother might set her heart on having a bishop, when, after all, the baby would be "only a girl."

We judge, on the whole, that pre-natal culture would be best secured by something in the high æsthetic line: letting the prospective mother, for example, lie behind a stained-glass window, in a Queen Anne room, on a pea-green sofa, and there study the dadoes and dream of faint lilies, with a sunflower reposing over the breast. This was not actually suggested by the Institute, however, nor was any formula for the production of robust and amiable boys and girls announced.

One speaker thought that there were about thirty per cent. of women who could make good wives and mothers. The remaining portion of women were about equally divided between those who can only make good wives or good mothers, or neither. Incidentally, a divine blessing was invoked upon old maids; loud and responsive applause revealed the social condition of a large part of the audience.

Only one incident disturbed the beautiful harmony of thought and progressive development of truth that was characterizing the meetings of the association. A medical man appeared upon the scene and criticised the Institute with a vigor and absence of periphrasis that very nearly produced a collapse. "How," said the doctor, "can a body of ignoramuses, who are possessed of the cheek of inspiration, try to settle points on which doctors and scientists are not agreed?" The speaker ridiculed the idea that bad fathers had bad children. He had seen women with bad husbands who had borne beautiful children. On the other hand, he had known the children of refined, educated, and highly respectable parents, to be devils from the start. If, said he finally, the members of the convention didn't know more about natural processes than appeared from their language, they had better hold their tongues.

Whether they did know more or not, the Institute adjourned next day *sine die*. It illustrated the result of an attempt of muddled and untrained minds to grapple with problems beyond their reach.

---

### DENTAL SURGEONS IN THE ARMY AND NAVY.

A MOVEMENT is on foot aiming to secure the appointment of dentists in the army and navy. It is understood that a bill for this object will be presented to Congress at its next session, and that the subject is to be brought up at the meeting of the American Medical Association in 1882.

The need of dental services in the army and navy was first urged some thirty years ago. The matter has been twice laid before Congress since then, but without any action being taken. A dentist has been appointed to the Naval Academy at Annapolis with the rank of Assistant-Surgeon, and this is, we are told, all that has been done in the matter.

The want of dentists for our soldiers and sailors is very apparent. Sound teeth are one of the physical requirements for service, and it is only right that opportunities for preserving the teeth should be given.

On sea-voyages and in Western service it is quite impossible, as things now stand, that there should be any way of treating diseased teeth except by extraction. The testimony of several of the medical staff of the army and navy, as given in the *Times* recently, is to the effect that the need of dentists is much felt.

There are a number of practical difficulties, however, in the way of creating and furnishing these services.

We have an army of only twenty thousand men, scattered in small garrisons throughout the country. It would hardly be feasible to appoint a dentist for each garrison, and the dental surgeon would have, therefore, to be a rather expensive itinerant. In the navy the difficulty would be still greater. In both branches there would, no doubt, be considerable opposition to admitting dentists to equal rank with medical men. For dentists have no right to call themselves medical or surgical specialists, unless they have gone through the same kind of education and training as that to which the gynecologist, laryngologist, or oculist subjects himself.

There is no doubt, however, that dentists are often needed and would be most useful in both army and navy. We should be glad to see the obstacles in the way of the introduction of their services there overcome.

---

REMOVING PLASTER JACKETS.—Dr. T. E. Wilcox, Assistant Surgeon U. S. A., finds the metacarpal and Hay's saws very useful for this purpose.

# Reviews and Notices of Books.

FASHION IN DEFORMITY, AS ILLUSTRATED IN THE CUSTOMS OF BARBAROUS AND CIVILIZED RACES. By WILLIAM H. FLOWER, LL.D., F.R.S., etc., Hunterian Professor of Comparative Anatomy, etc. London: Macmillan & Co. 1881.

IN this interesting little essay, the substance of which was delivered as a lecture before the Royal Institution of Great Britain, Professor Flower sets forth the follies of blind submission to the dictates of the tyrant fashion. The book is intended for the laity rather than the profession, as it forcibly explains what physicians are already quite familiar with, *i.e.*, that the modern propensity to deform certain parts of the body is scarcely less prevalent than was that of years ago. Civilization, it is well known, condemns the votaries of fashion to absolute physical miseries, which, especially in the female sex, become a potent cause for evil. The well-known crippling of the feet, resulting from wearing "fashionable" shoes, makes a very near approach to the Chinese custom which our civilization condemns and abhors. By long-continued tight lacing, and similar unnatural practices, Flower justly says that we put ourselves on a level, in point of taste, with the Australian savages, Botocudos, and Negroes.

THE THERAPEUTICS OF GYNECOLOGY AND OBSTETRICS, comprising the Medical, Dietetic, and Hygienic Treatment of Diseases of Women. Second Edition. Edited by WILLIAM B. ATKINSON, A.M., M.D. Philadelphia: D. G. Brinton. 1881. 8vo, pp. 571.

THIS work comes to us in the second edition, enlarged, revised, and improved. It is decidedly one of the most useful volumes that the general practitioner can have within his reach.

TRANSACTIONS OF THE AMERICAN GYNECOLOGICAL SOCIETY, for the Year 1880. Vol. V. Boston: Houghton, Mifflin & Co. 1881. 8vo, pp. 382.

THE fifth volume of the Transactions of the American Gynecological Society is filled with interesting material, not only for the specialist, but for the general practitioner. Although the number of papers is not so great as in former volumes, the subjects treated of are in greater variety, and, if possible, of more practical character. The articles, without exception, are evidently prepared with much care, while the discussions of the subjects are of such a character as to bring out all the salient points. The address of the president is timely, and touches upon many points of interest to the society. Dr. Battey, of Georgia, discusses, ex-cathedra, the proper field for Battey's operation. Dr. Geo. J. Engleman, of St. Louis, cites two cases of anterior displacement of ovary for which Battey's operation was performed. Uterine massage as a means of treating certain forms of enlargement of the womb is pointedly discussed by Dr. A. Reeves Jackson, of Chicago. Dr. Henry P. C. Wilson, of Baltimore, Md., treats of ovariotomy during pregnancy, and Dr. Theophilus Parvin presents, with equal thoroughness, the subject of secondary puerperal pregnancy. Three cases of death from rupture of the uterus with laparotomy are detailed with accompanying remarks by Dr. William J. Howard, of Baltimore, Md. "Occlusion of the Gravid Uterus" is the title of an article by Dr. Joseph A. Eve, of Augusta, Ga. Dr. Geo. J. Engleman, of St. Louis, communicates a most interesting and exhaustive account of the posture in labor assumed by different nations, and at different periods. The paper is profusely illustrated, and is filled with most curious and interesting statements. It is decidedly one of the most interesting articles we have read for a long time. The hot rectal douche is quite practically treated of by Dr. Jas. R. Chadwick, of Boston, as is also the subject of the induction of premature labor by William L. Richardson, of Boston, Mass. Dr. Henry F. Campbell, of Georgia, has an interesting communication on quinine in gynecic and obstetric practices. Dr. W. H. Byford reports a case of successful extirpation of the kidney, while Dr. C. D. Palmer concludes the series of papers by an excellent article on laparo-hysterotomy. The volume is published in its usual elegant style, and is a triumph of the typographic art.

PRACTISCHE BEITRÄGE ZUR KINDERHEILKUNDE. I. Heft. Pneumonie und Pleuritis. Von DR. ADOLF BAGINSKY, in Berlin. Tübingen: Verlagder H. Laupp'schen Buchhandlung. 1880. (Practical Contributions to the Therapeutics of Children. Vol. i. Pneumonia and Pleurisy. By DR. BAGINSKY, of Berlin. Tubingen: H. Laupp's Publishing House. 1880.

WITH this volume Dr. Baginsky initiates the publication of the results of his investigations and observations at the Clinic for Sick Children in Berlin. Since the year 1872 three thousand one hundred patients have obtained medical attention at this institution.

The subjects taken up in the present number are pneumonia and pleurisy. As regards the differentiation of catarrhal and croupous pneumonia, the author sides with Henoch, Steiner, Gerhardt, and others, who declare that, in a certain number of cases, a distinction is difficult, and at times impossible. The author hopes to be able to prove that there are numerous instances in which there can be no doubt as to the individuality of each form, so dissimilar are they in onset and general course. On the other hand, cases are not infrequently observed which it is impossible to classify. There are cases in which the seat of the disease, its extension, and the course of the fever furnish no guide for a decision whether the disease be croupous or catarrhal pneumonia. Lobular pneumonia may assume the character of croupous, while, on the other hand, lobar pneumonia may present the type of the catarrhal affection. At times there appears to be a combination of both forms, still further complicated by caseous and tubercular changes in the inflammatory products. In the majority of cases, however, a differential diagnosis between croupous and catarrhal pneumonia can be established. To that form in which such a distinction cannot be made the name of mixed pneumonia is applied.

Dr. Baginsky, in common with other writers, finds that croupous pneumonia occurs more frequently on the right side than on the left (fifty to thirty-four). His observations also corroborate the experience of Ziemssen, that the upper lobe of the right side is more frequently affected than that of the left, while the opposite holds good as regards the lower lobes. No explanation is offered for this fact.

Under the head of croupous pneumonia, the author refers to various anomalous forms of this affection, *e.g.*, abortive pneumonia, wandering pneumonia (pneumonia migrans), gastric pneumonia, and cerebral pneumonia (Rilliet and Barthez).

The second part of the first volume treats of pleurisy. According to Dr. Baginsky, simple uncomplicated pleuritis is quite a rare affection in children, he having seen but twenty-one cases in his clinic.

Should the character of these contributions be sustained, the work bids fair to become an interesting addition to pædiatrics.

CHEMICAL ANALYSIS OF THE URINE, BASED IN PART ON CASSELMANN'S ANALYSE DES HARNS. By E. F. SMITH, Ph.D., and JOHN MARSHALL, M.D. Philadelphia: Presley Blakiston. 1881.

THE student of to-day must often be sorely puzzled in his choice of a guide-book for elementary instruction in the various departments intimately or remotely related to medicine. The existing works on urinary analysis, for example, are scattered in untold numbers over the land. But the supply of such manuals continues to satisfy imaginary wants. The student is supposed to be ever exclaiming, "I want a guide-book," and, with Byron, we may call this

> —— "An uncommon want
> When every year and month sends forth a new one,
> Till, after cloying the gazettes with cant,
> The age discovers it is not the true one."

However, we mean no disparagement of the labors of Smith and Marshall. Their attention is devoted mainly to the chemical side of the subject, and their association with students has enabled them to prepare a practical and reliable little reference book. Those who are already the fortunate or unfortunate possessors of a similar work will hardly care to purchase the present volume, even if it contains some chemical details not found in their manuals. Those who are yet without a guide-book for urinary analysis will find this a useful and welcome aid.

PROCEEDINGS OF THE CONNECTICUT MEDICAL SOCIETY, 1881. Nineteenth Annual Convention, held at Hartford, May 25th and 26th. New Series. Vol. II. No. 2.

THE volume before us contains a more than usual amount of interesting matter. The report of the Committee on Matters of Medical Interest presents the results of some studies regarding phthisis, which show that it is apparently increasing among the foreign born of the State. The Committee on Lunacy Commissions gives an account of the history and uses of these organizations in this country and elsewhere. It inclines to the opinion that they should be tried more extensively in the United States. Dr. Seguin's paper on epilepsy has appeared in THE RECORD. The report upon malaria in the Connecticut Valley has also been noticed by us. There are several articles upon lacerations of the cervix, as well as a number of miscellaneous contributions, which are short and interesting.;

THIRD ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF THE STATE OF RHODE ISLAND, for the Year ending December 30, 1880.

THIS report contains the vital statistics of the State in full. There is also a valuable and somewhat novel feature in the report on cattle diseases. There are no special papers, however, on sanitary subjects.

FIFTH ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF WISCONSIN, 1880.

THERE are several good papers in this volume, and the report of the State Board's work shows it to be an active and useful organization. The subjects of school hygiene, kerosene, diseased meat, recreation, and the study of hygiene are treated of by various contributors. These make the report a valuable sanitary document.

# Reports of Societies.

## NEW YORK PATHOLOGICAL SOCIETY.

*Stated Meeting, November* 9, 1881.

DR. GEORGE F. SHRADY, PRESIDENT PRO TEM.

### EPITHELIOMA OF THE NECK.

DR. RIPLEY presented a specimen with the following history, furnished by Dr. Terriberry, house surgeon: J. S——, seventy-three years of age, was admitted to Charity Hospital, October 7, 1881. The patient had always had very good health. He had had syphilis, but there was no present evidence of the disease. He had been in the habit of drinking alcoholic drinks up to eight years ago. In his early life he served as a sailor, and during that time he lost his left leg. Twenty years ago he had typhoid fever, from which he fully recovered. About twelve years ago, while convalescing from varioloid, he noticed a small "bleb," about one-eighth of an inch in diameter, at the apex of the left occipital triangle. It was painless, slightly raised above the surrounding integument, hard to the feel, and from it oozed a watery material on squeezing. At the end of five years this sore was about half an inch in diameter, and had the same general features, except that it was more solid than when it first appeared. About three years ago it began to grow more rapidly than it had done formerly. Two months ago it began to ulcerate upon the top and to grow rapidly. On admission there was a flattened tumor two inches in diameter, situated at the apex of the left occipital triangle, and abruptly elevated above the surrounding skin to the height of half an inch. It was freely movable. The surface was partially ulcerated, and had an odorless, sero-sanguinolent discharge, the unbroken portion being smooth and shining. The growth was somewhat indurated. It was not painful, nor was there any evidence of inflammatory action in the tissues surrounding it. There was no neighboring glandular enlargement. The patient's general condition was unfavorable; his appetite was poor; his lungs were the seat of vesicular emphysema; he had headache, some vertigo, blurred vision, and constipated bowels. A portion of the growth was removed and examined microscopically by Dr. Ripley, and found to be carcinoma of the epithelial variety.

On October 14, 1881, the patient was anæsthetized, and Dr. Terriberry, house surgeon, removed the tumor, together with a small portion of the muscular tissue by which it was surrounded. No vessels were ligated. The wound was dressed during the first twenty-four hours with picked lint wet in carbolic acid, one drachm to the pint; afterward with balsam of Peru and oakum. On November 7th, the case was progressing favorably, and the open sore was only an inch in diameter in one direction, and half an inch in the other, and had a healthy granulating surface.

Dr. Ripley remarked that he presented the specimen for three reasons: 1st, on account of the unusual chronicity of the disease; 2d, on account of its not having given rise to constitutional symptoms; and, 3d, because the cervical lymphatic glands were not involved.

DR. GERSTER referred to two specimens of amputated legs which he had presented to the Society.

The amputations had been performed on account of elevated ulcers of the character presented in Dr. Ripley's case, and which had persisted for eighteen and thirty years respectively without causing much discomfort beyond local irritation, and without causing any generalization of the disease or infiltration of the glands in the vicinity of the local lesion. From those cases, and from that reported by Dr. Ripley, he assumed that the tumors were not originally of a cancerous character; that they were of a benign character, and had gradually taken on a malignant form. He remembered one such case, where an Austrian officer had a large wart upon his back which was constantly irritated by the strap which held his sword. That wart became ulcerated, and subsequently a very malignant cancer, and finally destroyed the life of the soldier. Certainly it was against the experience of pathologists and clinicists that cancer should exist for twelve, sixteen, or even eighteen years, without killing the patient.

Dr. Ripley, in reply to Dr. Gerster, referred to a case which he had about twelve years ago. The patient came to him with a tumor of the breast which she had had for eighteen years; but it had recently commenced to grow rapidly, and he amputated the breast, together with an axillary gland. The tumor was carefully examined microscopically, and it was found to be true cancer in which original nodule had undergone extensive fatty degeneration, thus showing that the structure had taken on a retrograde action. He also referred to cases observed by Dr. Barker, in which epithelioma of the cervix uteri had been under observation for twelve years; and Dr. Emmet had also reported cases in which epithelioma of the cervix had existed eight, six, and four years. He did not dispute that such tumors may have been originally of some other character, but there was no proof in his case that the disease had ever been anything else except cancer. He believed that there had been no proof in many cases that the so-called warts were simply warts. Many of them were not examined with the microscope, and they may have been malignant disease in a state of rest, and in that condition the patient carried them for years. He had operated upon a case in Charity Hospital, three or four years ago, in which epithelioma had lasted for several years, when suddenly it began to grow very rapidly and he removed it entirely, and at the same time removed a large portion of the parotid gland. After the operation the patient gained in flesh and the wound healed almost entirely, when the disease began to sprout out rapidly and carried off the man within a few weeks. Because a tumor grew slowly and then developed rapidly, did not prove that it was cancerous from the beginning. At the same time Dr. Ripley believed that tumors might change their character. He also wished to add that he believed with Billroth and other observers, that people did not have cancers from bruises or wearing sword-straps upon their backs, unless there existed in the constitution a tendency to the malignant disease. Such irritants might develop the cancer more speedily, but in those patients the cancer would eventually develop spontaneously.

Dr. Wiley referred to a case in which it was said that there was cancerous disease of the cervix uteri twenty years ago. The patient remained in exactly the same condition, and when only a few years ago he saw her he diagnosticated laceration of the cervix, operated, and the wound healed kindly. He supposed that there was no cancer about it, but cancer afterward developed, was operated on, and, so far as he knew, the disease had not returned. He had seen very old cases of laceration of the cervix in which there was no evidence whatever of cancer, and he had reached the conclusion that these lacerations did not produce cancer, although they might produce a very great amount of irritation. If persons were to have cancer, they would have it whether they had laceration of the cervix or not. He believed that that had been proved satisfactorily.

Dr. Wyeth thought that it had been settled that irritations did produce cancer; as, for example, in carcinoma of the intestines the disease appeared at those points in which the ingesta passed through very narrow openings, where the greatest irritation was produced. Besides, the parts of the external body most subject to irritation were the most liable to cancerous disease. There might be a predisposition to the disease, but he thought that it was an established clinical fact that irritation produced, as well as precipitated, the malignant disease.

Dr. Ripley thought that the location of the disease might be decided by the irritation, but that the cancer itself was not caused by the irritation.

Dr. Wyeth remarked that it had not always been proven that predisposition to the malignant disease existed.

### LABOR AT FULL TERM—SUBSEQUENT CONDITION OF THE PLACENTAL SITE.

Dr. Ripley also presented the uterus, obtained through the courtesy of Dr. L. L. Seaman, chief of staff at Charity Hospital, removed from the body of a married woman, twenty-eight years of age, who gave birth to her second child, October 25, 1881, at the Maternity Hospital. The following history was furnished by Dr. Chas. H. French, house surgeon: The labor was normal. October 31st, on account of fright, she suddenly sprang from her bed, and was with difficulty quieted. Shortly afterward she complained of intense pain in the lower part of the abdomen and back, and severe headache. Poultices, morphia, and an ice-cap were ordered. On October 30th (day previous to the fright) her temperature was 100° F. in the morning and 101½° in the evening, and respiration 32°.

October 29th.—Temperature, 100° F.; pulse, 88 to 96; respiration, 28.

October 28th.—Temperature, 100° F.; pulse, 80 to 90; respiration, 28 to 24.

October 27th.—Temperature, 98⅓° F.; pulse, 68 to 70; respiration, 20 to 24.

October 26th.—Temperature, 98½° F.; pulse, 72; respiration, 24.

On October 31st the temperature in the evening was 104⅓° F.; pulse, 104; and respiration, 33.

November 1st.—Abdomen, very tender, but especially in the inguinal regions and lower portion. Tympanites; thighs flexed at intervals. Evening temperature, 104° F.; pulse, 132; respiration, 34. Morphia was continued. During the night the temperature fell to 102⅓° F., pulse to 120, and respiration to 20. Vomiting was a persistent symptom.

November 2d.—At 4 A.M., the patient had a severe chill, and shortly afterward her temperature reached 105⅘° F.

The patient died at 7 A.M. November 3d.

The autopsy was made by the curator, Dr. Putzel. The body was well nourished. The heart was normal. The entire lower lobe of the left lung and a portion of the upper lobe were in the red-hepatization stage of pneumonia. The spleen was large and

soft. The liver was the seat of chronic interstitial hepatitis. The kidneys were normal. The abdomen was tympanitic. The right Fallopian tube was enclosed in a layer of plastic exudation. The uterus reached as high as the top of the symphysis pubis. At the placental site there was an elevation four inches in diameter, and half an inch high, and its surface was uneven, and presented a granular appearance.

Dr. Ripley presented the specimen with special reference to a discussion which occurred between himself and Dr. Garrigues, concerning the condition of the inner surface of the uterus at the placental site a short time after labor, say one month (see MEDICAL RECORD, vol. xx., p. 496).

The appearance of the mass occupying the old placental site was very similar to that observed in the specimen presented by Dr. Watson, the variations being that it was a little larger, in some places thicker, and its surface more uneven. These differences were probably mostly due to the difference in their ages—one being a month old and the other only eight days. From the few works on obstetrics which he had consulted, he had been unable to obtain any information in regard to this interesting question; but Cornil and Ranvier, in speaking of the changes which take place in the uterus following delivery, describe a granulating surface left after the expulsion of the placenta, which subsequently breaks down and is discharged; and they think it a probably slow process by which the parts at this point are regenerated. They quote Slavjanski as having recently described papillary vegetations, analogous in structure to granulation tissue, in the uterus of a young woman three months after delivery. Dr. Ripley was therefore of the opinion that these masses were mostly made up of granulation tissue, and not of retained placenta. In a medico-legal point of view, as was suggested by Dr. Watson's case, it was important to ascertain whether they were normal or abnormal. The specimen presented he regarded as cumulative proof of the correctness of his statement at a previous meeting that they were, at least, of common occurrence.

DR. BRIDDON referred to specimens presented to the society by Dr. T. C. Finnell, in which there was uniformly an elevated and circular area of tissue at the placental site. They were specimens for the most part obtained after abortions. There was no evidence as to whether the mass was placental or granulation tissue.

DR. WYLIE remarked that it had been stated repeatedly that it was wrong to leave any placental tissue within the cavity of the uterus, and he asked Dr. Ripley if he thought it was a common practice to allow it to remain. He regarded the condition present in Dr. Ripley's specimen as one due to puckering of the tissue from uterine contraction with subsequent granulation. It was wrong to leave placental tissue attached, as it was very liable to give rise to hemorrhage and possibly septicæmia.

DR. RIPLEY was glad that Dr. Wylie had asked him the question, because it gave him an opportuunity to correct an inference which possibly might be drawn from the report of his remarks made at the meeting alluded to—that is to say, it might be inferred that he did not believe in removing portions of placenta, whereas his practice was the most positive in that respect; and if there was any evidence whatever that a portion had been retained, he invariably dilated the cervix uteri, if necessary, and examined with reference to that point.

The society then went into executive session.

## NEW YORK NEUROLOGICAL SOCIETY.

*Stated Meeting, December* 6, 1881.

DR. T. A. MCBRIDE, PRESIDENT, IN THE CHAIR.

BEFORE the paper of the evening was read, DR. T. A. MCBRIDE, having asked Dr. Seguin to take the chair, moved a suspension of the by-laws in order to allow Dr. Burchard to make a personal explanation. The motion being carried, DR. BURCHARD said that he wished to offer some corrections regarding the report of a case of

REFLEX PARALYSIS FROM GENITAL IRRITATION,

made by him at the last meeting of the society. He had at that time said that Dr. McBride saw the case in consultation, and pronounced it one of reflex paraplegia from phimosis, which was the diagnosis made by himself and Dr. Lente. Dr. Burchard then read the full history of the case as recorded in his notebook at the time. By this it appeared that Dr. McBride had not considered it a case of paraplegia, but one probably of spinal irritation from phimosis.

The paper of the evening was then read by DR. V. P. GIBNEY, it being entitled

INTERMITTENT SPINAL PARALYSIS OF MALARIAL ORIGIN.

Dr. Gibney proceeded at once to relate the histories of certain cases, showing, as he thought, this form of disease:

Case I. was that of a boy seven years of age. He was one of three children, the others being healthy; father intemperate, mother nervous. Family lived in a very malarious neighborhood. In September, 1878, he had a high fever, with delirium at night, and suffered from pains in the limbs, and hyperæsthesia of the surface. This continued for a week. He took much quinine. He improved, then got worse again; was finally left with paralysis of the four extremities not quite complete. There was some faradic reaction. Diagnosis: myelitis of anterior horns. He was admitted to the hospital later. He then showed marked genu valgum; walked with difficulty, and legs far apart. Diminution in power of some of the muscles; relaxation of posterior ligaments of knee; knee phenomena normal; tendo Achillis tense.

Treatment, electrical and mechanical; no medicines given. Gradual improvement took place—so much, indeed, as to cast doubt over the diagnosis of spinal paralysis, from a pathological standpoint. The boy left the hospital cured.

He returned later with nearly the same history as that given before, but the attack this time was less severe. He had been living in a malarious locality. Ordered quinine and faradism. Under this he was completely restored again.

He returned to the malarious locality. After a time he began to have chills; was improved by quinine, but finally was brought to the hospital, in June, 1880, for a third time, severely paralyzed. He suffered much from pains in the limbs, and he had a fever. The fever gradually disappeared; the electrical reactions were very feeble; the patient gradually improved, and became able to walk about; electrical reactions also became stronger. By August he was nearly well. In October he was worse again; his limbs became paretic; he was unable to walk; improvement soon after set in.

Dr. Gibney here referred to the fact that intermittent spinal paralysis was very rare indeed. A case was reported in 1857, by Macario, of a woman who

was taken with paralysis of the extremities and tongue, two days after confinement. These symptoms were repeated in a quotidian type for three days, and were cured by quinine. Two other cases are quoted by Erb. One, reported by Hartwig, was that of a vigorous laborer, aged twenty-three, who had had tertian ague for five weeks, five years before. Since then he had been well. He was gradually attacked with paralysis, and in four days all his extremities, as well as the trunk and neck, were paralyzed; sensibility was intact; this lasted twenty-four hours; it then let up, the patient perspiring freely. For twenty-four hours patient was well; then symptoms all returned. For over seven months intermissions or remissions of health, or improvement alternated with paralysis. Quinine and arsenic lengthened the intervals of health sometimes to four days or more. At the end of seven months no radical improvement was present, and the termination of the case is not known.

A case of intermittent tetany is reported by Dr. Wilkes. The literature of

MALARIAL POISONING

is full of neuroses. Trousseau thought that very nearly all the symptoms in masked malaria could be explained by referring them to the effect of the poison on the nervous system. The speaker thought it not difficult, therefore, to suppose that malarial poison might cause an anterior poliomyelitis. In such cases the anatomical diagnosis is the same as in ordinary spinal paralysis; but, pathologically, there is a different condition, and the prognosis differs materially.

In Dr. Gibney's case the first attack occurred in September, 1878, six days after an attack of intermittent fever. Partial recovery took place. In September a second attack occurred, from which recovery was not complete till the next January. Quinine was not given. The third attack occurred five weeks after the cure of the second. Recovery took place in three weeks. The fourth attack occurred four months after recovery from third. He was discharged in six months perfectly well. Six months later he had a fifth attack coming on gradually with pains in the limbs. Improvement was slow, and now, after four months, he is not yet cured.

Case II. was that of a boy aged six. He was admitted to the hospital with paralysis of the legs, and hyperæsthesia. Electrical reactions good, but not vigorous. No real atrophy. Two years before he had lived in a malarious locality, and was taken suddenly ill with fever and pains in the limbs. Was sick for six weeks, his limbs becoming paralyzed. He recovered in a few weeks.

In April, 1880, he had a second attack, which began with *malaise*. He gradually lost power in his limbs. Being brought to the hospital, he slowly improved. September 24th he was discharged cured. The next spring he was taken again with paralysis in all four extremities. Two weeks later he had convulsions. He died finally of exhaustion. He did not have tuberculosis. No autopsy was made.

Dr. Gibney, in commenting on the preceding cases, said that he thought that pathologically there must be some difference between them and those of ordinary spinal paralysis. In studying them he had been struck with the symmetrical development of the symptoms which occurred in all cases. In no instance had he found the typical degenerative reaction. Dr. Seguin had said that if cases of infantile spinal paralysis did not recover in two or three months, there was very little hope for them. Dr. Gibney could not recall a single case in which complete recovery had taken place. He was inclined to believe that simple active, followed by passive hyperæmia, occurred in the cases of intermittent spinal paralysis. Such a condition of congestion might vary under the action of the malarial poisoning, just as was the case with the spleen.

The theory of a multiple neuritis might be entertained.

Dr. M. Putnam-Jacobi, being called on to open the discussion, said that she had seen Dr. Gibney's first case. She was puzzled by it then, but felt even more so since hearing the history just given. When she first saw the case she was struck with the fact that the child complained of pain all the time, and it was pain which made him object to walking more than his muscular inability to walk. He did not complain of pain upon firm rubbing, but upon slight touches. Her first thought was of hysterical paralysis or partial paralysis. Only, the electrical reactions could not be obtained, or were not good in some muscles.

Comparing this case with two of those cited by Erb, there seemed to the speaker to be a marked difference between them. In the latter the paralysis was very temporary and of a quotidian type. Quinine promptly cured the attacks. Romberg refers to the sudden appearance of paraplegia in cases of pernicious malarial fever.

In Dr. Gibney's case, 1st, the paralysis did not come on suddenly; 2d, it lasted for some time, and did not intermit as in intermittent fever; 3d, it did not terminate in sweating; 4th, there were marked sensory disturbances; and 5th, the paralysis was not complete; in all those respects differing from the cases quoted by Erb. In Macario's case the paralysis was not referred by that author to malaria, but was thought to be an idiopathic form, distinct from the hysterical. There is one form of paralysis to which Dr. Gibney's case might be referred, and that is the rheumatic. This is a most common form of functional paralysis. The point against such a diagnosis was the electrical reactions, which were not those of a functional paralysis.

Dr. E. C. Seguin said that Dr. Gibney's last case was so different from the first that it might be referred to a different cause, perhaps that of a diffuse neuritis.

The speaker then enlarged upon the extreme rarity of cases of paralysis from malarial causes. In many extensive treatises the disease is not mentioned, or, as in Niemeyer, is barely referred to. Neither Erb nor Hertz (in Ziemssen) report any cases of their own. Nash and Leyden report cases. Macario stole his case from another author.

The speaker was inclined to take the same view as Dr. Jacobi regarding Dr. Gibney's case. It seemed to be one of a relapsing rather than intermittent character. In these cases it would be nearer the truth to say that malaria caused the fever, and the fever the paralysis.

Dr. Seguin then read a case of his own:

The patient, a man, fifty-five years of age, had passed through a period of overwork and anxiety. He had had no distinct ague. He complained of headache, numbness of the right arm and leg, and more or less of the whole right side of the body. He did not seem very ill. Was of full habit. A prescription was given. He returned in two weeks saying that he was better, but still had headache, with numbness and a jaded feeling in right side

every other day. Quinine was given and recovery took place within fourteen days. He thought the case might be termed one of

INTERMITTENT POST-MALARIAL HEMI-NUMBNESS.

DR. A. D. ROCKWELL related the history of a man of middle age who suffered from an

INTERMITTENT HEMIPLEGIA.

He was first taken suddenly with complete right hemiplegia; articulation imperfect, mind clear. He recovered in a few months. He was then taken with a second attack, not so severe as the first. He could walk a little. After this he was taken every other day in the same manner for three or four weeks. The paroxysms then changed in character. After some variations in his condition, the hemiplegia became complete, more serious symptoms set in, and he soon died. Post-mortem showed some organized lymph upon the pia mater of the brain; choroid plexus enlarged and cystic; considerable serous effusion at the base of the brain; liver fatty; also the mitral valves. No rupture of arteries, and no embolism or thrombus in the brain. A diagnosis of the old-fashioned kind would be serous apoplexy. Dr. Rockwell thought it plausible to suppose that there was an intermittent spasm of the cerebral vessels, which might account for the paralyses. Quinine was given on account of the intermittent character of the attacks. Electricity was also used.

As regards

MALARIAL PARAPLEGIA,

he had seen two unmistakable cases.

DR. L. C. GRAY dwelt upon the fact that Dr. Gibney's case was more of a relapsing than intermittent type. If a case did not have any characters of periodicity it was hardly right to say it was malarial. The speaker had never seen a case of paralysis due to malaria, but he had seen cases which apparently had such an origin. The history of such a case was then related. Dr. Gray thought that in the next ten years the attempt would be made to show that malaria is a neurosis. Already several authors had shown a leaning in that direction.

DR. BIRDSALL inquired whether there were any qualitative changes in the electrical reactions. He was told that at one time there was, in one of the cases.

Some further remarks were made by Drs. Seguin, Putnam-Jacobi, and Gray. The society then adjourned.

---

ÆSTHETICS AND CATHARTICS.—Bunthorne, the "fleshly poet," in the new opera "Patience," gives the following as "a wild, weird, fleshly thing, yet very yearning, very precious. To understand it, cling passionately to one another and think of faint lilies:"

What time the poet hath hymned
The writhing maid, lithe limbed,
  Quivering on amaranthine asphodel,
How can he paint her woes,
Knowing, as well he knows,
  That all can be set right with calomel?

When from the poet's plinth
The amorous colocynth
  Yearns for the aloe, faint with rapturous thrills,
How can he hymn their throes,
Knowing, as well he knows,
  That they are only uncompounded pills?

It is, and can it be
Nature hath its decree,
  "Nothing poetic in the world shall dwell?"
Or that in all her works
Something poetic lurks,
  Even in colocynth and calomel?
    I cannot tell.

# Correspondence.

## ANOTHER WORD FOR DR. BEARD.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: My attention has been called to a letter from Dr. William A. Hammond in your issue for the 15th of October last, criticising a letter which Dr. J. Crichton Browne has communicated to the *British Medical Journal* "relative to the experiments in hypnotism by Dr. Beard before a medical audience at the Waterloo Hotel in London."

Those who are best acquainted with Dr. Hammond's own controversies will be more able to attach a correct value to his opinion respecting the fairness and temperateness of this discussion. I will not venture to criticise Dr. Hammond's letter for the sake of the *tu quoque* argument; but as I was present by Dr. Beard's invitation at the experiments referred to, and as I have read the correspondence thereupon, I must beg you to allow me to express my entire dissent from Dr. Hammond's opinion as to the want of fairness, kindness, and consideration shown to Dr. Beard, and as to the insulting character of the questions proposed to him in Dr. Crichton Browne's letter.

At the *seance* itself, Dr. Crichton Browne was most punctilious in assuring Dr. Beard that the examination as to character to which his "trained subject" was subject, was no expression of doubt in Dr. Beard's own good faith; and, so far from the questions put in the letter being intended as insulting, they were evidently intended as the offer of a capitulation with all the honors of war. For Dr. Beard does undoubtedly owe to the gentlemen whom he called together to witness his experiments the apology of a confession that he had been deceived; and to say that it is insulting to ask for such an apology is but a new instance of abusing the plaintiff's attorney when there is no case.

Such tactics are not likely to succeed when the abused person is well known in the court for his habitual fairness, kindness, and consideration. Nor, indeed, has Dr. Beard as yet adopted such tactics; but in his absence and silence they have been adopted by one who assumes to know "with accuracy his character and mental methods," because, forsooth, no one has had more frequent occasion to differ from and to come into antagonism with him. But the wide circle of scientific men who know Dr. Crichton Browne's character and mental methods from a better point of view than such hostile experience, would, I am sure, vouch that he is incapable of intending insult to any one, and least of all to an American physician present in this town as a professional guest.

But enough of this personal question. Underlying it is one of far greater importance which it must not be permitted to conceal—a question affecting the very foundation of all experiments correlated with those of the Waterloo Hotel.

*What bearing has the moral character of the subject of experiment in hypnotism, and the synonymous or allied isms, upon the credibility of the phenomena?*

According to the answer we accept, Dr. Crichton Browne was right or wrong in exposing the character of Dr. Beard's trained subject, and in his subsequent questions to Dr. Beard. If it does not matter whether the subject of experiments upon consciousness is truthful and trustworthy, or one who

may be passing under a false name, according to Dr. Hammond's supposition, because "he may have stolen a sheep and is afraid of the myrmidoms of the law," then Dr. Crichton Browne's method was wrong, and his interrogations of the trained subject superfluous. Dr. Beard says, and Dr. Hammond approves, that "the moral character of the individual is no factor in the case; all that is requisite is a man or a woman of some kind." And Dr. Hammond goes still further in comparing the arguments against hypnotism with "those applied a hundred years ago to Jenner."

But such assumptions ignore the consideration that the phenomena of hypnotism are not merely physiological, but that they are also psychological, and that the question of consciousness or unconsciousness, which is invariably and inevitably involved in them, cannot be involved in such experiments as those by which Jenner established the value of vaccination.

It might be true that the worst man in the world, if he could be found, would be an hypnotic subject. But, if so, how could you distinguish his real state of hypnotism from the fraudulent representation of hypnotism which he might have assumed? Dr. Hammond writes as if he considered that the absence of the demonstration of pain from injury is a sufficient test; but one would have thought that his experience as an army surgeon among malingerers would have made him doubt this test. Have we any physiological test whether pain is felt or not—that is to say, in this inquiry, whether unconsciousness is real or feigned? I think not; and that the conditions of the inquiry compel us to take into consideration moral probabilities, and hence the necessity for some knowledge of the character of the subject.

I beg you to understand, sir, that I write these lines without prejudice. Dr. Beard and Dr. Hammond are not personally known to me, but the inquiry in which they are engaged is one in which I have taken a deep interest for a length of time, which may perhaps antedate even their experience. Forty-four years have passed since I saw Dr. Elliotson's hypnotised patients, the Misses Okey, in University College Hospital. They certainly were impostors when they declared that they saw Black Jack sitting on the foot of any bed on which a dying patient lay; but Dr. Elliotson believed in them, and sacrificed himself for his belief. Three or four years later I saw a number of hypnotised patients at Elliotson's private house, whom I did believe and still do believe were not impostors; but I arrived at this conclusion upon data of moral probability alone, and not from any physiological test. These data were that I found a number of epileptic patients coming to Elliotson's house daily to be hypnotised for the relief of their malady without fee or reward given or received, and without the slightest publicity. It was at a time when public interest in the matter had withered down to its roots, and Elliotson assured me that he never in his life had received a fee from or for any mesmerised patient; and I quite believed him. The circumstances did not present to my mind—which was quite sceptical enough—any appreciable motive for imposture.

Since then I have seen a good deal of mesmerism and of hypnotism, which is the synonyme for its simpler forms, and a great part of it, I am convinced, upon moral data, was flagrant imposture. Last year, however, I had an experience which brought Elliotson and his patients vividly back to my memory, in the observations which, through the kindness of Monsieur Charcot, I was able to make of his patients at the Salpetrière. Their abnormal states of unconsciousness seemed to be far more varied than those of Elliotson's epileptics, and I should be indeed surprised if the accomplished physician who was investigating them, had been willing to eliminate the moral character of each patient as no factor in the case.

When one thinks of the deceptions habitual to hysterical patients, of the stoical endurance of pain for the smallest reward or advantage which one sees in jugglers, malingerers, fakirs, etc., and when one reflects that states of consciousness are absolutely the secret of those in whom they occur, it does seem to me incontrovertible that phenomena connected with or attributable to abnormal states of consciousness cannot be appreciated with any satisfactory degree of exactness without some knowledge of the moral character of the hypnotised subject.

This principle may perhaps not be difficult to accept, but its practical application will certainly not be effected by mere politeness and circumlocution. In the meanwhile, I think that the profession in America will be inclined to endorse the vote of thanks to Dr. Crichton Browne which was passed in the hall of the Waterloo Hotel for his skill in unmasking an imposture which would have been contemptible if it had not been fraught with mischief in the example it might have set to the imitative and neurotic public.

I am, Sir, your obedient servant,

JOHN CHARLES BUCKNILL.

THE ALBANY, LONDON, ENG.

## HYPOPHOSPHITES VERSUS PHOSPHATES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: A comparative statement of the amount of phosphorus contained in hypophosphites and phosphates, showing the superior power of hypophosphites over phosphates as a carrier of this element, and accompanied by a brief statement, showing *why* hypophosphites are the best assimilants of phosphorus.

(O=8.)

| Hypophosphites, 100 parts by weight | Phosphorus Per cent. | Phosphates, 100 parts by weight. | Phosphorus. Per cent. |
|---|---|---|---|
| Lime | 36.47 | Lime (bone phosphate) | 18.46 |
| Soda | 35.10 | Soda (cryst'd tribasic) | 8.61 |
| Potassa | 29.75 | Potassa (neutral tribasic) | 17.67 |
| Iron (ferrous salt) | 33.33 | Iron (ferrous tribasic) | 17.22 |
| Quinia | 8.33 | Quinia (neutral tribasic) | 4.20 |
| Zinc | 23.25 | Zinc (neutral tribasic) | 14.72 |

Also a table showing the percentage by weight of oxygen necessary to be absorbed by the phosphorus element of the hypophosphites to convert them into phosphates, while the latter, being already fully oxidized, absorb none.

(O=8.)

| 100 parts by weight of hypophosphites of oxygen. | Per cent. |
|---|---|
| Lime, to convert into phosphate, must absorb | 37.65 |
| Soda, " " " " " | 36.24 |
| Potassa, " " " " " | 30.71 |
| Iron, " " " " " | 34.41 |
| Quinia, " " " " " | 8.60 |
| Zinc, " " " " " | 24.01 |

As hypophosphites become oxidized, the relative proportion of phosphorus contained in the resulting compound becomes less by the increase in weight of the substance, and the power to absorb oxygen (to which property the therapeutic value of these salts are due) becomes less and less, until, when fully oxidized to the condition of phosphate, their efficacy as phosphorus assimilants cease, unless it can be proven that phosphates become partly deoxidized in the economy—a result highly improbable, when it is considered that the natural tendency of vital action is in the contrary direction, and that phosphorus is always excreted in its highest oxidized form (phosphate).

Even if it be admitted that phosphates *are* partly deoxidized in the body, this, if shown, only proves that the element ought to be in that condition to fulfil its physiological province, and would, of itself, be the strongest argument in favor of the use of hypophosphites, and thus anticipate natural requirements. While it will not be denied that all remedies should be *pure*, there exists a special reason why hypophosphites should be in that condition—this is, that impurities, particularly those of inorganic character, prevent the favorable action of these remedies. The presence of slight traces of impurity in many medicinal substances does not, as a rule, greatly interfere with their action; but this rule *does not* apply to the hypophosphites, as is evidenced by the experience of *all medical men* who have *obtained the best results* from their use. Physicians who have not sufficiently investigated this subject would be surprised at the difference in results, if they would use only chemically pure salts; nor should they be administered in *combination* with other remedies, as cod-liver oil, malt-extract, etc. These remedies, if indicated, should be given alternately, and not simultaneously with the hypophosphites.

Respectfully,
R. W. GARDNER.

NEW YORK, December 9, 1881.

## REGULATING THE PRACTICE OF MEDICINE.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR: I would like to inquire whether the Pennsylvania law, disabling medical graduates from schools in other States can stand? If so, would it be well for other States to retaliate in kind? and would it be any less in harmony with our institutions if other State legislatures should specialize against graduates of Pennsylvania institutions? I do not wish to appear as asking these questions, but thousands of your readers would be glad if the RECORD would shed some light on this matter.

Yours very respectfully,
T. CLARKE MILLER.

MASSILLON, O., November 5, 1881.

[We do not understand that the Pennsylvania Act in any way disables graduates from foreign schools; it simply requires that such graduates shall satisfy the local authorities as to their competence, which is a perfectly proper regulation. Section 4 of the Pennsylvania Act is as follows: "*Any person who may desire to commence the practice of medicine or surgery in this State after the passage of this Act, having a medical diploma issued, or purporting to have been issued, by any college, university, society, or association in any other State or foreign country, shall lay the same before the faculty of one of the medical colleges or universities of this commonwealth for inspection, and the faculty being satisfied as to the qualification of the applicant and the genuineness of the diploma, shall direct the dean of the faculty to endorse the same, after which such person shall be allowed to register as required by Section 2 of this Act.*"

The foregoing is an almost exact reproduction of one of the sections of the New York Medical Act of 1880, and is perfectly constitutional and proper, for the several States have the undoubted right to regulate the manner in which any business, trade, or occupation shall be carried on within its borders, though it cannot, of course, discriminate against citizens of any particular State. The object of medical legislation in any given State is to provide that none but competent men shall practise there. If the colleges within the State graduate incompetent men, the State can revoke their charters; but this, of course, it cannot do as regards colleges without the State, and hence is obliged to adopt some other means of assuring competence in those who practise within its borders.

We believe it would be well for other States to incorporate similar provisions in their medical acts, though the idea of *retaliation* should not be thought of in this connection. It is simply a question of protection to the people against the influx of so-called graduates of institutions which, until of late, flourished in Pennsylvania, and against institutions nearly as bad, which, we believe, are still in operation in Ohio.—ED.]

# Obituary.

## DR. CHARLES H. STILLMAN,

PLAINFIELD, N. J.

CHARLES H. STILLMAN, M.D., of Plainfield, N. J., died at his residence in that city, December 11th, of heart disease. He was born in Schenectady, N. Y., January 25, 1817, graduated at Union College in 1835, then came to New York, and entered the office of the late Prof. Edward Delafield, with whom he studied medicine, graduating from the College of Physicians and Surgeons in 1840.

For two years after his graduation he was physician and oculist to the Eastern Dispensary, but poor health obliged him to leave New York, and he settled in Plainfield, where he continued in practice until his death.

He was a permanent member of the American Medical Association, a member of the New Jersey State Medical Society, and ex-president of his County Medical Society, but his chief ambition was connected with the development of the public school system, having founded the first public school of his State, and at the time of his death had held the position of President of the Board of Education in Plainfield since its formation. He had been for many years district surgeon of the Central Railroad of New Jersey, and possessed great skill as a surgeon. He had been identified largely in the growth and prosperity of Plainfield for the past forty years of his residence, had been its mayor, and was a director in several of its banks and other institutions.

He leaves one son in the profession, Dr. Charles F. Stillman of this city.

# New Instruments.

## A VAGINAL DEPRESSOR.

By HENRY J. GARRIGUES, A.M., M.D.,

NEW YORK.

NOMINALLY the different kinds of specula may be counted by scores, but going by principle there are scarcely more than three: the tubular (*e. g.* Ferguson's), the bi- or multivalvular (Cusco's, Nott's, Bogeman's, Byrne's, Meadows', etc.) and the univalvular. The tubular and valvular forms were known to the ancients; the univalvular, in connection with the left-lateral position of the patient, by which gravitation and air-pressure are utilized, is the great invention of Dr. J. Marion Sims which has opened new fields for operative interference, and given, for the first time, a view of the vagina and part of the uterus in their natural relations.

The tubular speculum is the most imperfect of all. It is not only unfit for almost all operations, but it gives in many cases so erroneous an idea of the vaginal portion, that Dr. Emmet would scarcely have been able to discover the laceration of the cervix, and much less point out the surgical remedy for it. It pushes the uterus far away, out of reach of the finger, it shows only a small part of the vagina at a time, and it is difficult to cleanse. It seems to me that the time has come to do away altogether with this antiquated instrument, which in every respect is inferior to the other kinds at our disposal.

Of all specula with two or more valves I prefer Cusco's. It is easily introduced, it gives a good view of the vaginal portion, and, in many cases, of a part of the cervical canal; it keeps, in most cases, the folds of the vaginal wall sufficiently on the stretch to prevent them from bulging in between the valves, and hiding from view the deeper parts. It is not expensive, and it is easy to clean. But, like all multivalvular specula, it stretches the roof of the vagina a good deal; nay, so much that sensitive patients with some kinds of pelvic inflammation cannot stand it. Except in such cases, I find Cusco's speculum the most convenient in the great majority of office patients.

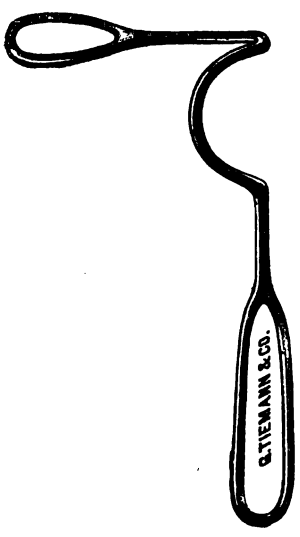
The other multivalvular specula present each some advantages over Cusco's, especially in regard to greater operations.

The most universally useful speculum is Sims'. I do know any operation on the vagina or uterus in which it cannot be used, and in some it is indispensable. Even in common private and dispensary practice involving diagnosis and application of drugs to diseased parts, it presents immense advantages. It merely lifts the veil which covers the vaginal portion. It allows us to use the sight and the touch simultaneously. It gives less pain than any other, and it is the easiest of all to clean.

The only drawback in this admirable instrument is the necessity of employing not only an assistant, but one who has particular experience with its use. An inexperienced person cannot hold it in such a way that the surgeon can do his work undisturbed. It is claimed that the necessary presence of a third person is a moral guarantee; but the fact is that many patients, and that some of the most prude, prefer to be alone with the physician during a vaginal inspection, and few are the physicians who have so large a gynecological practice that they can afford to keep a nurse for this purpose alone. The great majority of general practitioners, and many gynecologists, use therefore other specula, except for certain operations. Many contrivances have been invented by Emmet, Noeggerath, Pallen, J. B. Hunter, Erich, Studley etc., in order to make Sims' speculum self-retaining and render the assistant superfluous. I have myself derived much benefit from Erich's speculum which takes the shoulder of the patient as the fixed point (*Baltimore Physician and Surgeon*, September 1, 1874). But all these instruments are expensive, take much time to adjust and to clean, and frighten the patient more or less. They are therefore not adapted to general use for simple examinations or applications.

In many women who have had frequent sexual intercourse, nothing more is required, to see and to treat the common diseases of the vagina and cervix-uteri, than to put the patient in Sims' position and use his speculum; but in other cases it is necessary besides this, to move the cervix with a hook or depressor. In this case both hands of the physician are in use, and it becomes impossible for him to do more than look at the parts.

In my dispensary-practice where I have quite a number of patients to treat within a short time, and no kind of assistance, I found that Sims' speculum served a better purpose than anyother, and in the cases alluded to, I helped myself for a long time by applying a curved pair of forceps to the anterior lacunæ, and hold it with the left hand, together with the speculum; but the forceps made both inspection and application of drugs to the cervical canal troublesome. Lately I was shown a new tongue-depressor, where the shaft was deflected to one side so as to lie in one of the angles of the mouth. As soon as I saw this instrument it struck me that, by some modifications, it would make a most excellent vaginal depressor to be held in the same hand as Sims' speculum. Thus the instument represented in the drawing was originated, and since, I have found in practice that it works admirably. It is used in the following way:



The patient being in Sims' position, and his speculum having been introduced, and being held by the full left hand, the knuckles turned upward, the patient is directed to elevate the right nates. The depressor is seized with the right hand. Its heart-shaped anterior end is applied to the anterior lacunæ, and slightly pressed against the anterior vaginal wall. The arched part is turned upward, the handle is placed in front of the mesial part of the speculum, *and the two together are held with the left hand.* The arc allows an unobstructed view, and the right hand is free, so that it can be used for applying instruments to the uterus. Since there are no screws or joints, both the speculum and the depressor are easily introduced, easily withdrawn, and easily cleaned. The depressor and the speculum together, cost less than most bi- or multivalvular

specula. Thus everybody is enabled to secure all the advantages of Sim's speculum in every-day practise without the necessity of employing a skilled assistant. If the use of the patient's own hand to hold up the nates should be objectionable, any assistant, unskilled as well as skilled, can do it for her.

It was to be expected that similar contrivances had been invented by others. When I showed mine in the New York Obstetrical Society, Dr. Frank P. Foster exhibited an instrument which he occasionally had used, during a couple of years, for the same purpose, and Dr. Leopold Meyer, of Copenhagen, has shown me another, which has been invented by the Danish physician Fanoe. I do not lay claim to have made a great invention, and I will not dispute anybody's priority; but I am sure that if the profession will try the instrument here described, they will find it as useful as simple.

137 West Twenty-second Street.

## ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from November 27, 1881, to December 10, 1881.*

Murray, Robt., Colonel and Surgeon. Medical Director, Military Division of the Missouri. The leave of absence granted him in S. O. 100, October 5, 1881, Military Division of the Missouri, extended two months. S. O. 272, A. G. O., December 2, 1881.

Summers, Jno. E., Lieut.-Colonel and Surgeon. Medical Director of the Department. Granted leave of absence for 25 days. S. O. 123, Department of the Platte, December 1, 1881.

Wright, P. J., Major and Surgeon. The leave of absence granted him in S. O. 229, November 8, 1881, Department of the Missouri, extended 20 days on Surgeon's certificate of disability. S. O. 123, Military Division of the Missouri, December 2, 1881.

Lauderdale, J. V., Capt. and Asst. Surgeon, McPherson Barracks, Ga., before complying with par. 3, S. O. 124, C. S., Department of the South, granted leave of absence for one month, with permission to leave the Department. S. O. 136, Department of the South, December 8, 1881.

Perley, H. O., Capt. and Asst. Surgeon. At the expiration of his present leave of absence report in person to the Commanding General, Department of the East, for assignment to duty. S. O. 274, A. G. O., December 5, 1881.

Johnson, Richard W., First Lieut. and Asst. Surgeon (recently appointed), to report by letter to the Commanding General, Department of Dakota, for assignment to duty. S. O. 272, C. S., A. G. O.

Small-Pox in the West.—The State of California is reported to have quarantined against Chicago in order to prevent the introduction of small-pox. Trains on the Central Pacific Railroad had introduced small-pox into five different counties in California.

The Chicago health officers say that if California quarantines against Chicago, Chicago will have to quarantine against New York.

In this city there have been over 270 deaths from small-pox in the past six months, but only about 75 of these occurred in the past three months (ending December 10th).

Practising without a Diploma. — Edward B. Lighthill, of No. 6 West Twenty-ninth Street, was fined $100 recently for practising without a diploma. Five other cases have been indicted by the County Medical Society.

The New York Medico-Legal Society held its stated meeting December 7th. A paper was read by Dr. J. G. Johnson, of Brooklyn, entitled "Anæsthetics Medico-legally Considered." Regarding the question whether it was right to employ anæsthetics to detect fraud, as in cases where men feigned deafness or crooked spine, etc., to escape detection. The lecturer held that such practices were wrong and reprehensible when done against the will of the prisoner, as it was compelling him to make admissions which would criminate him.

The discussion of the paper was postponed to allow the members to proceed to the annual election of officers, but it was considered of so much importance that it was determined to make it a special subject of discussion at the February meeting of the society. The balloting for officers then began. The four candidates for President each received twenty-eight votes, and the election of that officer was postponed until the next meeting. The following are the other officers elected: First Vice-President, Dr. C. A. Leale; Second Vice-President, D. S. Riddle; Secretaries, Dr. George W. Wells, Charles P. Bull, and Dr. J. F. Chauveau; Librarian, Max F. Eller; Treasurer, E. C. Harwood; Chemist, Dr. C. A. Doremus; Curator and Pathologist, Dr. William R. Birdsall; two Trustees to fill vacancies, Drs. C. S. Wood and J. T. Davies; Members of the Permanent Commission to fill vacancies, Austin Abbott, Dr. R. J. O'Sullivan, and Dr. Wooster Beach.

A Bust in Marble of Dr. G. A. Otis, U. S. A., has been placed in the Army Medical Museum by his brother officers.

On "Hospital Saturday" nearly 1,000 ladies sat in the London streets in charge of the collecting boxes.

Dr. Patrick J. Clarke.—The death of Dr. Patrick J. Clarke, of this city, occurred on December 5th. For more than twenty years the deceased had been attending physician to St. Vincent's Hospital, and the esteem in which he was held at that institution has been expressed by a resolution of appreciation and regret passed by the Medical Board. Dr. Clarke was born in Ireland in 1826. He came to this country in 1845. He graduated from the College of Phy-

sicians and Surgeons in 1849, and remained in the active practice of his profession up to the time of his death. Dr. Clarke served with credit as an army surgeon through three years of the war of the rebellion. He accompanied the Sixty-ninth Regiment, New York Volunteers, to the war, remained with it as long as the regiment was in service, and was subsequently stationed for some months at Fort Hamilton. Dr. Clarke was widely known and esteemed by his brother practitioners in the city.

DR. JOHN H. STEVENS, Stonewall Jackson's principal surgeon in the late war, was found dead in his office at Dallas, Texas, November 25th. He was a Virginian, but had lived at Dallas since the war.

PHOTOGRAPHS OF THE LEADING MEDICAL MEN present at the International Congress are to be published by Mr. Barraud. As many as five hundred pictures have been prepared.

SIR ERASMUS WILSON.—Erasmus Wilson, President of the Royal College of Surgeons, England, has been knighted.

ANOTHER ASYLUM CONFLAGRATION.—The State Institution for Idiotic and Imbecile Youths, near Columbus, O., was recently burned. The fire fortunately occurred at meal time, and all the inmates were marched out without trouble. This is the third asylum that Ohio has lost by fire.

DR. SAMUEL A. GREEN, the City Physician, has been nominated for Mayor of Boston by both the Republican and Citizens' convention. This is a high yet deserved tribute to a much esteemed physician.

NOTE OF CORRECTION FROM DR. HUGHES.—Dr. C. H. Hughes, of St. Louis, writes: "In your report of the proceedings of the Tri-State Medical Society I am reported as speaking highly of static or franklinic electricity as a therapeutic agent, whereas I commended only the constant galvanic current as the best tranquillizer and tonic in neuralgic and hyperæmic states. I have no such experience with franklinic electricity as would justify an opinion."

PROF. L ELSBERG, M.D.—The trustees of Dartmouth College have elected Dr. Louis Elsberg, of New York, Professor of Laryngology and Diseases of the Throat in the Dartmouth Medical College. Dr. Elsberg having resigned the professorship he has heretofore held in the medical department of the University of the City of New York.

THE JOURNAL OF NERVOUS AND MENTAL DISEASES, edited during the past eight years by Drs. Jewell and Bannister, of Chicago, Ill., has been transferred to Dr. William J. Morton, of New York, who will have active editorial control of it, and will be aided by a number of prominent neurologists in this and other cities.

ADMINISTRATION OF TINCTURE OF IRON IN CAPSULES.—Dr. J. H. Grimes writes (*Medical and Surgical Reporter*) that a most successful and agreeable way of giving the muriated tincture of iron is to drop it into an empty capsule, the cap is then replaced, and the dose swallowed without any trouble. Some water should be taken at the same time.

ALBUMEN WATER.—This has been recommended as a good substitute for milk and beef-tea in cases where these substances disagree with the patient, or could not be obtained. The preparation is largely used by the French. It is made by dissolving the white of one or more eggs in a pint or two of water, sweetening with glycerine, and flavoring with orange-flower water. It may be taken cold and used *ad libitum*. It is an excellent food in typhoid fever and typhoid dysentery.—*Chemist and Druggist.*

THE KENTUCKY STATE MEDICAL SOCIETY has offered a prize of $50 for the best essay embodying the results of original experimental research, or original clinical observation on the nature, mode of propagation, pathology, and treatment of scarlet fever. The competitors must be members of the State Medical Society.

A NEW dwarf was exhibited recently at the Academy of Medicine, Paris. He is thirty inches high, weighs eighteen pounds, and is fourteen years old. His head was pronounced by M. Jules Guérin to be an example of "microcéphalie généralisée." His intelligence is about the average of boys of his age. His parents are French peasants and are well grown people.

STATIC ELECTRICITY AS A GALACTAGOGUE is recommended by Dr. W. R. D. Blackwood (*Philadelphia Medical Times*). He bases his belief on successful results in three cases which he tried. Sparks were passed through the breast daily.

A CORRECTION IN DR. THOMAS' CASE OF DOUBLE UTERUS.—A misleading statement was made in our report (December 3, 1881, p. 626) of Dr. Thomas' case of double uterus. It was reported that "Attention was drawn to the possibility of future insemination through the abdominal opening."

In relating the history of the case to the class at the College of Physicians and Surgeons, a by-stander asked, whether, this being an uterus with an ovary attached, if an ovum were deposited within it, impregnation of that ovum would be possible, to which Dr. Thomas replied affirmatively.

ALUMNI ASSOCIATION, MEDICAL DEPARTMENT, UNIVERSITY OF THE CITY OF NEW YORK.—The eleventh reunion dinner of the Alumni will take place at Delmonico's, corner of Fifth Avenue and Twenty-sixth Street, on Thursday, January 12, 1882, at 6.30 o'clock P.M. The price of tickets is ten dollars each, and they may be obtained of any member of the committee or of the secretary. The sixteenth annual business meeting for the election of officers, and for the transaction of such other business as may be presented, will be held at the same place on the same evening at 6 o'clock. T. R. Varick, M.D., President, 239 Washington Street, Jersey City; Frederick R. S. Drake, M.D., Secretary, 8 West Thirty-fifth Street.

A HOSPITAL SUNDAY IN BALTIMORE is wisely advocated by the *Maryland Medical Journal.*

EXTIRPATION OF PAROTID GLAND.—Dr. A. C. Post writes: "In the report of the proceedings of the New York Academy of Medicine, in the number of the RECORD for December 3, 1881, I am incorrectly represented as saying that in a case of extirpation of the parotid gland which I had reported, it was not known positively that all of the gland was removed. The statement which I made was that in undertaking the operation I did not know that the tumor involved the parotid gland, but I had no doubt in the end that I had removed the gland. The external carotid artery and the facial nerve were imbedded in the tumor, and portions of them were necessarily excised."

# Original Lectures.

## METHODS OF DIAGNOSIS IN DISEASES OF THE NERVOUS SYSTEM.

By E. C. SEGUIN, M.D.,

CLINICAL PROFESSOR OF DISEASES OF THE NERVOUS SYSTEM IN THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

(Phonographically Reported for THE MEDICAL RECORD.)

### LECTURE II.

GENTLEMEN: In my last lecture I spoke of the objective part of a diagnosis, and pointed out in brief the principal disturbances of function which we are able to recognize in an examination, and exhibited and described the instruments by means of which we detected and measured the degree of such disturbances. I referred to certain methods of diagnosis which fall within the province of other specialties, more particularly the use of the ophthalmoscope. To-day I wish to extend my remarks to certain other methods of diagnosis, a knowledge of which is essential to the success of the nervous specialist. Among these may be mentioned auscultation and percussion in the physical examination of the chest and abdomen, the use of specula and tuning-forks in the examination of the ear and testing the hearing, the use of the laryngoscope in the examination of the larynx, the chemical and microscopical examination of the urine, and so on.

Of course the neurologist cannot be expert in all these methods of examination; but, on the other hand, he cannot be expected to make a satisfactory study of his patients without a certain degree of skill in these diagnostic manœuvres. With respect to urine, it is especially important that he should be able to make a satisfactory examination of it. I may say that I have often had occasion, during the past five or six years, to prove the dependence of an obstinate and severe form of headache upon the existence of contracted kidneys. Detecting the presence of an excess of phosphates, or of an excess of urea, or the condition known as oxaluria, is often a very important factor in nervous diagnosis. It is not sufficient to make a single examination of a sample of urine in a test-tube, by boiling it and adding acid, but the amount of urine secreted in twenty-four hours should be known, and, from repeated examinations of it, the existence or non-existence of morbid conditions noted.

By an examination of the genital organs, both male and female, much important information may be derived.

A knowledge of the presence of versions, flexions, or tumors of the womb, ovarian disease, deep-seated stricture, or narrow anterior urethra, and many other abnormal conditions of the genital tract, will lead to the adoption of appropriate treatment; whereas, without such knowledge, drugs may be prescribed and electric batteries used, for an indefinite time, without relief.

I next propose to speak of the principles of diagnosis, and will divide the disorders to be diagnosticated into two classes, organic and functional. This division presupposes a difference in the method of examination. The logical difference between the two methods of study is very marked. The complete and satisfactory recognition of organic diseases of the nervous system involves a triple diagnosis. It is arrived at inductively by means of the history given by the patient, by means of the testimony of friends, by means of the various methods of physical examination, and, to a certain extent, deductively by knowledge you have acquired from experience, books, etc.

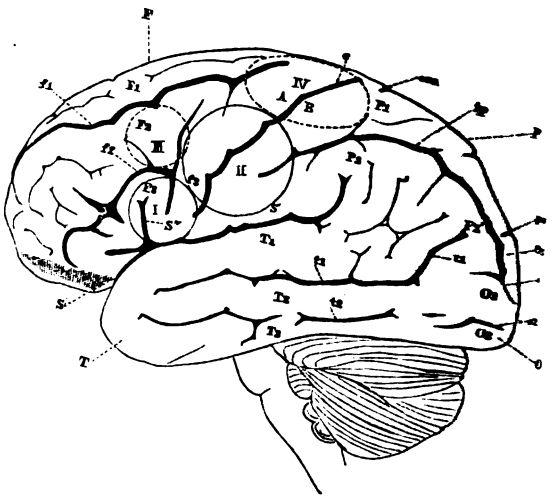
The first diagnosis is that of the symptoms, and these may be considered as constituting what the Germans call the "symptom-group." Second, we make a diagnosis of the location of the lesion, and it is this diagnosis which is just now interesting observers most. In the third place, we have to determine the nature of the lesion, which is, perhaps, of the greatest practical importance to the physician. We first determine the symptoms, next the situation of the lesion producing the symptoms, and afterward try to determine the pathological nature of the lesion.

The first diagnosis is made exclusively from a history of the case and an objective examination. We learn from the statements of the patient and friends, and an ocular examination, what has taken place during the few days or weeks preceding. We determine, by methods pointed out in the last lecture, whether there exists paralysis, spasm, ataxia, anæsthesia, and so on. The mental symptoms to be noted are loss of memory, delusions, or uncontrollable manifestations. We thoroughly overhaul the person of the patient physically and psychically, and we determine what functions are well performed, and which are interfered with. During the next few weeks you will have in every lecture an illustration of how to make this diagnosis: for example, a patient will come into the clinic complaining of weakness of the muscles of the face, arm, and leg, upon one side of the body. We determine the existence of this condition by the testimony of the patient and his friends, by inspecting the patient, by the application of tests which have already been described to you, and from the data thus collected decide that the case is properly one of hemiplegia. Again, a patient may come in complaining of weakness of both legs, while the arms are normal, and we decide that he is suffering from paraplegia. A patient presenting with no paralysis and no anæsthesia, but with an inability to direct the movement of his legs, we say is suffering from inco-ordination or ataxia. If a patient presents with one eye turned outward and a drooping of the lid, we designate this condition as one of ptosis with strabismus. If a patient has loss of sensibility, we call it anæsthesia, and ascribe particular names, in accordance with the distribution of the anæsthesia. When anæsthesia of one-half of the body exists, we call it hemi-anæsthesia. If, upon examination, vision is found to exist only in one-half of the visual field, we call the condition one of hemiopia. In this manner we indicate the condition of the various organs throughout the body, and determine in what way they differ from the normal, and to the conditions found to exist we give certain names which represent the symptom-group. Sometimes we are only able to discover a single symptom, and have to go on to the next diagnosis. My observations have led me to believe that, in making the first diagnosis, the testimony of the patient is too frequently used as a sufficient guide, and pains are not taken to go over the body and carefully determine the extent of paralysis, ataxia, or areas of anæsthesia, and make a record of what is found. There is often a lack of definiteness in examinations of nervous cases which practitioners would

not allow in chest diseases. From the time of Laennec no physician has considered his examination of the chest complete without having determined the nature and character of the signs, so that he could tell another physician what he had seen or heard, in such a way as to lead him to a correct diagnosis. We are attempting to apply the same exact method to the study of nervous diseases, and are making very great progress.

The second diagnosis, that of the location of the lesion, is of importance. It is not directly dependent upon observations made with our eyes, instruments, etc., but upon anatomical and physiological knowledge. It is very seldom that a nervous lesion is visible, except in cases resulting from injury or external violence. We have to determine the situation of the lesion from the symptoms present, by means of our acquired knowledge of physiology and anatomy. Hence it is that exact and minute anatomical knowledge is more essential for the diagnosis of nervous diseases than for that of any other.

I will take up some of the symptom-groups of which I spoke a few moments ago, as determined hypothetically in my remarks: for example, that of hemiplegia. We revert to our acquired knowledge concerning the nervous supply of the paralyzed parts derived from the spinal cord and brain. We also revert to the experiments made upon the central nervous system of higher animals within the last fifteen years, and our empirical knowledge of lesions discovered after death in cases of hemiplegia studied during life. For the present I will rely more particularly upon anatomical and experimental data. We know that the limbs of one side of the body receive innervation from the opposite side of the brain. You will hear it said that this law is not valid; but I say to you it is a good law, and a knowledge of it will be of great help to you in the study of nervous diseases. The few exceptions which are quoted in support of the idea of its invalidity are capable of many interpretations which leave the law untouched for all practical purposes. I propose to discuss this matter of the crossing of nerve-fibres from one side to the other, in a subsequent lecture. Bearing in mind, then, that either side of the body is innervated from the opposite side of the brain, we at once locate the lesion on the opposite side from that in which the paralysis is found to be present in our hypothetical case of hemiplegia. Partly from the study of anatomy, partly from the study of embryology, and partly from a knowledge of what recent experimental physiology has taught, we know that the whole of one side of the brain has not the power of moving all the opposite side of the body. Let us suppose a case of left hemiplegia with the lesion in the right hemisphere. I may remark that the whole right hemisphere is not connected with the opposite cheek, arm, and foot. Recent experiments have shown that a relatively small part of the right hemisphere has power over the left cheek, hand, and leg, and this part of the hemisphere is in the median region, and embraces a small number of convolutions—certainly not more than half of them. We have records of positive knowledge, to the effect that the anterior and posterior extremities of the hemispheres have no motor power over the opposite side. Still basing ourselves upon anatomical researches and physiological experiments, we know that the muscles of the left side of the face are innervated by a small part of the right frontal lobe; we know that the upper extremity is innervated by a small part of the brain known as the ascending frontal and parietal convolutions. We further know that the part of this right hemisphere which is connected with the leg is situated at a different point, nearer the median line, near and in the longitudinal fissure, and more posteriorly. In other words, we have determined with great accuracy the motor area of the right hemisphere, and the centres for the movements of the cheek, arm, and leg. With respect to the sensory function of the hemisphere our knowledge is not so exact, but we know that loss of sensibility on one side of the body indicates a lesion in the opposite half of the brain; that right hemi-anæsthesia indicates a lesion in the left hemisphere—one situated in all probability in parts posterior to the motor area. These are not theoretical



The above woodcut is modified from Ferrier: letters and figures the same.—S, fissure of Sylvius; c, fissure of Rolando; po, parieto-occipital fissure. A, ascending frontal gyrus; B, ascending parietal gyrus; $F_3$, third frontal gyrus; $P_2'$, gyrus angularis. Circle I., seat of lesions which (on the left side) cause aphasia. Circle II., seat of lesions which convulse or paralyze the upper extremity of the opposite side. Dotted Circle III., seat of lesions which probably convulse or paralyze the face on the opposite side. Dotted Oval IV., seat of lesions which convulse or paralyze the lower extremity of the opposite side. These districts receive their blood-supply from the middle cerebral artery.

guides; they are valuable life laws, and there has not a year passed, within the last five years, that I have not seen cases illustrative of them, and verified them by post-mortem examination. Bearing upon this point, I may say that I published two cases this year,* in which the diagnosis was made, by means of a knowledge of these laws, with such accuracy that we were within half an inch to one inch of the actual seat of the lesion. In a number of my cases the lesion has been found to be situated exactly where it was diagnosticated during life. Records of similar cases may be found in American, English, and Continental journals generally.

We are also able to locate, upon similar anatomical and physiological principles, lesions of the spinal cord. In paraplegia we can determine the height of the lesion quite accurately, by means of our knowledge of the points at which nerves are given off from the spinal cord. To quote a case: a patient falls and receives a dislocation and fracture of the seventh cervical vertebra, compressing the cord at this point. The patient at once presents anæsthesia and paralysis below the clavicles and in the distribution of the

* Journal of Nervous and Mental Diseases, July, 1881, p. 516.

ulnar nerve. Now, we know, from anatomical and some curious electrical * examinations, that the fibres of the ulnar nerve arise from the lower part of the cervical enlargement, and that its trunk is made up by the last cervical and first dorsal nerves. Hence it is that compression of the cord at this point gives rise to paralyses of parts supplied by this nerve. When I come to speak of the diseases of the spinal cord, I will give in detail the rules for determining the height of any lesion, by means of which a diagnosis of extreme accuracy can now be made. We can locate a lesion in the anterior and posterior portions of the cord, with reference to the white and gray matter. We know that paralysis, accompanied by great muscular atrophy and degenerative electrical reactions, is due to a lesion in the anterior gray matter of the spinal cord. We know that in ataxia of the legs and arms, in which there is no true paralysis, the lesion is strictly limited to the posterior white columns. A patient comes in with a stiff gait, with crossing of the legs, but without anæsthesia or ataxia; we are certain that the lesion is in the lateral columns. In peripheral paralysis, as, for example, when due to injuries of the nerves, a diagnosis is usually very easy to make, for we have an injury or scar to guide us. Or a nerve may be cut in a surgical manœuvre, and we can at once determine the seat of the lesion. But, in some cases, the seat of the lesion is not apparent, and we must judge of it by medical logic. In the diagnosis of such cases we are very much helped by an anatomical law, which you probably have not found in your books, and which summarizes the distribution of the sensory and motor filaments of nerve-trunks. I refer to the law of Van der Kolk, namely, that a spinal nerve gives its motor branches to the muscles as instruments of motion, and its sensitive branches to the part moved.† In other words, throughout the body the sensitive branches of a mixed nerve run to the part of the skin which is moved by the muscles receiving motor filaments from the same nerve-trunk. It is very easy to call to mind examples of this law. A sciatic nerve, for example, sends its sensory filaments to the calf of the leg and the foot, which parts are moved by the posterior thigh-muscles and both sets of tibial muscles, which receive their motor filaments from the sciatic. In the arm the musculocutaneous nerve gives motor fibres to the biceps and brachialis anticus, and its sensory filaments go to the integument of the forearm, which is the part moved by the above-named muscles.

Wherever you study this law, you will find it absolute. You may meet with some apparent exceptions, but they are only apparent. An apparent exception is found in the head, where the trigeminus plays the part of sensory roots for most of the cranial motor nerves. Studied in the light of this law, a patient presenting anæsthesia of the little and ring fingers, and outer part of the palm, with paralysis of the interossei and inner half of the thenar group, has a lesion of the ulnar nerve, probably above the wrist. If the flexor carpi ulnaris is paralyzed, the lesion is certainly above the elbow. Again, paralysis of the extensors of the carpus and fingers, with anæsthesia of the dorsum of the hand on its radial side, indicates a lesion of the musculo-spiral nerve.

We now come to the third diagnosis—that of the nature of the lesion. This should not be made until the others have been determined carefully; and, here again, we use entirely different principles of logic. This diagnosis is more empirical—more uncertain. The third diagnosis can be best made by the physician who has had the greatest experience with disease in general; and here comes in the strongest argument for the postponement of special practice until you have acquired a thorough knowledge of general pathology. It is just here that one realizes the insufficiency of normal anatomical and physiological study. It makes no difference what the symptoms are, or where the lesion is located, for that does not determine what the lesion is. Take, for example, a left hemiplegia with pafalysis of the left cheek, arm, and leg. The patient may have a tumor, a patch of softening, a hemorrhagic focus, a syphilitic formation; he may have what is exceedingly rare—local anæmia, and the only way of determining which one of these is present is by our knowledge of pathology. To this end, we determine the temperature, pulse, and other symptoms; the conditions of the arteries; the presence or absence of the signs of degeneration throughout the body, and the presence or absence of the signs of contracted kidneys and heart disease. To determine with certainty that a hemorrhage has taken place in the brain, you must ascertain the previous diathesis and the general condition of the body. The rupture of vessels in the brain is a mere accident; the same statement may be made in regard to softening. This latter condition is often due to organic cardiac disease, producing embolism of a healthy cerebral artery, and sometimes, also, of arteries at the periphery, which are more difficult to make out. It is likewise caused by local obstructions in the arteries of the aged or prematurely old, and of syphilitic subjects. The same general rules apply to the study of diseases of the spinal cord. The nature of the lesion is to be determined by the pathological condition of the patient, and by means of empirical knowledge acquired by post-mortem examinations. For example, if a child presents with enlargement of the head and separation of the sutures, we know, as a matter of experience and post-mortem examination, that there is internal hydrocephalus, the most common cause of which is tubercle; and we also say that it is probable that the tubercle is compressing the aquæductus Sylvii. In the same way we determine the difference between syphilitic and non-syphilitic subjects.

I go on, now, to the diagnosis of the functional disorders of the nervous system. This subject does not admit of as systematic a presentation as the former. In many of the functional diseases of the nervous system, we know very little about their pathology, so we do not complete the third diagnosis; and as the disease is functional, we need not consider the second. For example, chorea is an obvious symptom which we can recognize at a glance. If we attempt to localize the lesion or disease, we cannot go any farther than to make the statement that a functional lesion is situated in the brain, and that it is very probably a cerebral affection. We make this statement upon the remarkable fact that the disease is often hemiplegiform. We cannot go any farther, and, as regards the lesion of chorea, we are entirely in the dark. We can only offer speculations based upon a few post-mortem examinations, which, in my opinion, are worth very little. The same is true of epilepsy,

* In two or three cases of spinal irritation I have noticed that placing the cathode over the sixth and seventh dorsal vertebræ, with the anode near by upon an indifferent part, and passing a strong current, the patient, though devoid of any anatomical knowledge, has described a prickling sensation in the little and ring fingers of each hand. This is evidence of the cathodal excitation of the origin of the ulnar nerve.

† Schroeder Van der Kolk: On the Minute Structure and Functions of the Spinal Cord and Medulla Oblongata. Translation of the New Sydenham Society, pp. 6, 7. London, 1859.

hysteria, and neuralgia. The best we can do is to state the symptoms definitely, and not attempt any rigorous diagnosis of the disorder, or try to determine the nature of the lesion, in the same sense as we do lesions in organic affections. But yet there is a diagnosis to be made of the nature of the lesion, or, as I would put it, the condition of the patient. This consists, after we have determined that the patient has chorea, epilepsy, or neuralgia, or "neurasthenia," of making an inquiry into his general condition, the state of the circulation, arterial tension, and, in some cases, the action of the heart, and the condition and mode of action of certain organs which we know, from empirical knowledge, to be connected with functional disorders. For example, within the last seven years we have learned, with great positiveness, that certain cases of headache are due to straining of the eyes. In studying cases of headache, especially cases of long standing, it is desirable—I may say imperatively necessary—to study the condition of the eyes. Thanks to the labors of Drs. Weir Mitchell and William Thomson, of Philadelphia, we have been able to relieve a large number of cases of "bad head," as I call them. In the same way, with reference to hysteria, we examine the patient, not simply for anæmia and mal-nutrition, but also for uterine and ovarian disease or vulvar irritation. This will lead us many times to a correct understanding of the case. There is quite a large class of cases in which the symptoms are nervous, the patients experiencing a curious depression, pain in the back and head, aching in the limbs, and many other symptoms, chiefly sensory, all of which we are generally unable to refer to any definite cause, and they are known under the name of "neurasthenia." This name is all very well, provided we go farther. One theory as to the cause of these symptoms—and it is held by some very respectable authorities—is that they are due to a variation in the amount of blood in the spinal cord and brain. I myself confess to very little faith in this view. I think it can be shown that there can be but slight changes in the amount of blood present in the spinal cord, and that these are not accompanied with symptoms. My own experience is that the symptoms are often produced by conditions of general mal-nutrition, which can be classified conveniently under the heads of lithæmia, or sub-oxidation of the tissues. Some other cases are due to weak eyes, some to ovarian diseases, some to the use of tobacco, sexual excesses, etc. Cases of so-called hyperæmia of the brain, now so fashionable, are to be studied in the same way from the standpoint of the general physician; nearly all such cases being, according to my experience, resolvable into instances of lithæmia, eye-strain, cardiac disease, renal disease, irritation from the sexual organs, etc.; leaving exceedingly few cases of hyperæmia, if any. The diagnosis of lithæmia is to be obtained by the examination of the urine, and the usual method of doing this is very misleading. If the patient is told to bring a bottle of his urine, the first that is passed in the morning, it is found of high specific gravity, high color, acts upon litmus paper forcibly, and may deposit urates; or the microscope shows, in a few hours, oxalate of lime. To judge in this way from one specimen, I believe to be a most superficial practice. I am not willing to say that a patient is a subject of lithæmia or oxaluria, unless I have examined specimens of urine on successive days, for the reason that the urine varies from day to day, and during each day, owing to the varying conditions of the body. One or two examinations are of very little help. In my practice I make a number of examinations—three or four—of urine passed morning, noon, evening, and at bedtime; and I am unwilling to use the term oxaluria unless I find this condition indicated by most of the specimens. By this means the average condition of the urine in twenty-four hours can be determined.

I will make a few remarks in regard to taking the history of a case. Very few medical men take good notes. It is a very difficult matter to write a history so that different medical men, reading it, would come to the same conclusion in regard to the case. Of course we first obtain the patient's story. We have to guide the patient, so that we can arrange the facts which he gives us in some logical order. It is desirable, in many cases, to give some illustration as to the behavior of the patient, mental manifestations, etc. A few words with the friends of the patient, as to what they have observed, is often serviceable, and sometimes it is well to question the patient alone. In taking down the notes we form a dim mental outline of the diagnosis, in advance. It seems impossible to take a history without doing this. We next carefully record the objective symptoms presented by the patient, and thus reach what I have termed the first diagnosis. In some cases we may locate the lesion at once from the symptoms, and even determine the nature of the lesion. This is by no means infrequent, and the taking of the history will be the only time you need to give to the consideration of the case. In other instances you have to go on, step by step, and carefully determine the points in the diagnosis which I have referred to. We are often, in the course of this preliminary and semi-conscious notion of the nature of the case, led to doubt the patient's statements, and it is well to make a mental memorandum of these points, and, after the history is completed, question the patient again, or ask information of others. This is very necessary in cases where we investigate such causes as sexual irregularities and syphilis, family taints, etc.

---

THE PERILS OF THE OBSTETRICIAN.—The following amusing letter, which speaks for itself, was received by a leading gynecologist of this city: "I presume you remember the time, nearly four years ago, when you had attended my wife at the conception of her child. We lived at that event at —— West Thirtieth Street. You charged $20, which I paid you $10 on account. I intended to have paid you in full, but parties advised me not to do so, as you had not done an honorable act in hurting my wife. I now, knowing that my wife is in a verry precarious predicament from the effects of your hurried attention to her bringing forth the child, notify you that suit shall be brought against you should my wife die from said hurriness or negligence of duty on your part, I will do all I can to punnish you for this act. You gave her a milk leg—Indeed it was not so, but you closed a vein on the right of the womb. If you had taken time to do your duty, as a good doctor would have done, this would not have happened. Now, I hold you responsible for this; and, as my wife has just begun to suffer from it, I look to you as the guilty one.

"Verry Resp., R. J. M."

NOT IN THE CODE.—A physician in the town of Sturgeon, Mo., makes his round of calls in a buggy drawn by a pair of elks.

## AN ENTIRE CATHETER, OVER HALF A YEAR IN THE BLADDER, REMOVED PER URETHRAM.

By ROBERT ABBE, M.D.,

SURGEON TO THE OUT-PATIENT DEPARTMENT, NEW YORK HOSPITAL.

The subject of the following instructive case was a German, aged seventy years. He was in perfect health till November 24, 1880, when, after drinking a little too much wine at a wedding, he found on going home that he was unable to micturate. The overflow of his distended bladder dribbled away for three days, when a physician relieved the retention by a catheter, repeating its use, morning and evening, for several days. The patient then began to pass water very frequently, "every ten minutes, night and day." This condition has continued for nearly seven months, the intervals of micturition increasing, however, until of late he has held water half an hour. He had, during this time, been treated only for "catarrh of the bladder."

He lost flesh, became irritable, suffered pain, mostly through his hips and in the bladder, at the end of micturition, and passed a large quantity of pale urine loaded with muco-pus.

I searched the bladder, and at once detected what seemed to be a large stone. The prostate was not enlarged, but the posterior bladder-wall was much thickened.

The above were all the facts I could obtain from the patient up to the time of operation.

For one week I prescribed acetate of potash and tonics, until his bladder was less irritable, and he could retain urine three-quarters of an hour in the day time, and two hours at night.

On June 20, 1881, with the assistance of Dr. R. F. Weir and two students, I attempted to crush and remove the stone by Bigelow's methods and instruments.

The examination, under ether, gave promise of a "large stone," the searcher travelling over an extensive calculous surface.

For three-quarters of an hour we endeavored to grasp the stone and crush it, but succeeded in getting no bites in the jaws of the lithotrite larger than a fourth of an inch, and including at times what felt like bladder-wall with the calculus. The beak of the instrument was so immovably fixed when each seizure was made, as to leave no doubt that the bladder was caught, and hence to close tight the jaws of the instrument was unjustifiable. The main calculous mass seemed to elude the instrument, but was most conspicuous at the base on the left. We seemed driven to the conclusion that we had a large encysted calculus to deal with, and that lithotomy would have to be resorted to. At last, however, another small seizure was obtained with so free a play of the instrument in the bladder that it was safe to screw the jaws of the lithotrite tight. On removing it from the bladder, a small piece of old catheter was found to have been punched out, and brought away in the fenestrated jaws. The question, how to get rid of a calculus-encrusted catheter, more than half a year in the bladder, now presented itself.

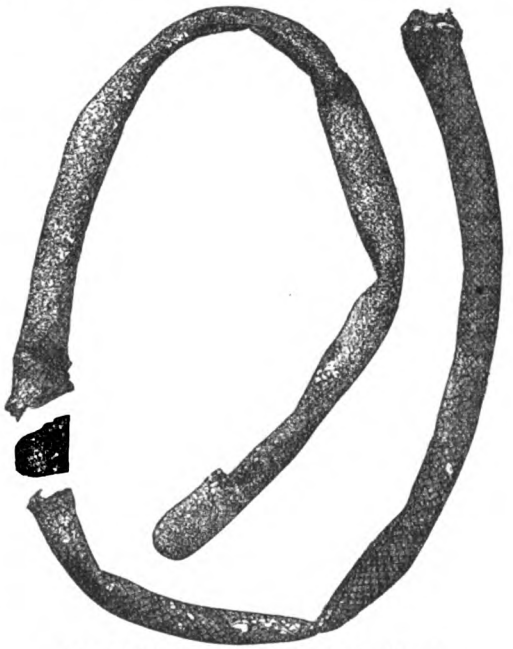
To avoid the more severe, yet simpler operation of lithotomy, I had either to proceed on the clue that the action of the lithotrite had given, and cut the catheter into small fragments, to be removed subsequently by the "evacuator," or drag it out by traction along the urethra. A twelve-inch catheter would require from fifty to a hundred seizures, under the most favorable circumstances, to cut it into one-fourth-inch pieces, and, in the present case at least, double that number. Considering the risks incident to this, the length of time it would require, and the uncertainty of detecting the last pieces of soft catheter, it was decided to seize it with the smallest Thompson's lithotrite and draw it out through the urethra. It was evident that the great number of gentle crushings it had already had must have denuded it of most of its crusting.

The smaller of the two fragments was seized one-third from its end, doubled on itself by traction, and firmly withdrawn.

The larger was caught near its centre. It was quite stiff, from salts deposited in its meshes, and came out with considerable rasping of the urethra.

The Bigelow evacuator (No. 31, French) was now introduced, the calculus-crusts washed out, and the operation concluded in an hour and three-quarters. The encrusting calculus, when dried, weighed forty grains.

The patient had severe urethritis on the following day, temperature 100½°, pulse 110, but on the second



Encrusted by forty grains of phosphatic calculus.

day, the acute symptoms subsided, and temperature and pulse were normal. On the third day urination was painless.

On the eighth day he presented himself at my office perfectly well, and holding his water three hours without pain. Two weeks later this interval was four hours, and he has since retained perfect health.

The patient says he had no idea of a catheter being in him, but from his son, a much more intelligent person, the following history was elicited:

The physician in attendance tied in a catheter on the Saturday evening after his first retention, to be left till Monday. On Monday morning the catheter

was missing when he awoke. The patient believed it had slipped out. His physician believed he had pulled it out in the night, and thrown it out of the window. Another physician saw him in consultation, and, failing to feel it in the bladder, told him it could not be there, or, if it was, it would dissolve. He therefore dismissed it from his mind. He began to pass water every ten minutes, but thought it part of his trouble of the previous week, and had since believed he had catarrh of the bladder, no subsequent search being made.

The following considerations make it a case of much interest:

I can find only two cases where an *entire* catheter has remained in the bladder for anything like so long a period. One, recorded by Poulet as occurring in 1780, where a soft bougie, ten months in the bladder, was doubled into a knot and formed the centre of a calculus ʒ ijss. in weight; removed by lithotomy. The other, by Fergusson, who, in 1863, removed an entire bougie (No. 6, English), which had been *two months* in the bladder, and had acquired a slight crusting of calculus. He used a small instrument fashioned like a lithotrite, and was fortunate enough to seize the bougie by the tip, thus not doubling it at all on itself. He had at that time known of no similar case.

Dr. Bigelow, in 1867, removed two-thirds of an elastic catheter, *four* weeks in the bladder, grasping by a small lithotrite one inch from its end, and extracting it with the tip turned back. This patient had also been told, by his former attendant, that it would dissolve if left in.

In 1870, Dr. Buck removed an entire elastic catheter a few hours after it had slipped in. A small lithotrite grasped it at the middle, and it doubled in withdrawal.

Dr. Buck's case illustrates what has probably been often done with small instruments just after their slipping in. As early as 1849, Cæsar Hawkins, of St. George's Hospital, removed four inches of gutta percha catheter, soon after the accident, by lithotrite.

A number of cases are recorded of small scraps of catheter being cut up by the lithotrite, and evacuated by the patient. Thus, in 1858, Holmes Coote, at St. Bartholomew's Hospital, cut up four and three-fourths inches of bougie, soon after it had broken off in the bladder, and the patient evacuated it in a few days. He was of the opinion that the male urethra tolerates lesions too badly to allow of dragging such a fragment out by the lithotrite. In 1851, Dr. Buck had done the same thing with a piece four inches in length. He cut it into four pieces by a lithotrite, and the patient evacuated it.

Regarding the case I have reported, we have illustrated the notable tolerance of the urethra to comparatively rough usage, and its quick and complete recovery.

The catheter was effectually stripped of crusts, by gentle crushings, before its attempted removal. It was an English gum-elastic, woven catheter (No. 10, English). The gum, of course, entirely dissolved.

---

M. Vulpian and M. Paul Bert.—M. Bert having been appointed Minister of Public Instruction, M. Vulpian, in consequence, resigned his position as Dean of the Paris Faculty of Medicine. This was on account of a variance of opinions between these gentlemen. M. Béclard, Professor of Physiology, has accepted the vacant position.

## MAMMARY CANCER.*

Excision—Recurrence of Growth in Cicatrix—Successful Treatment by Electrolysis.

By ROBERT NEWMAN, M.D.,
New York City.

In January, 1881, Dr. Charles F. Stillman had the kindness to transfer to me a lady patient, suffering with a malignant tumor of the breast, with the request to give her electric treatment. The patient presented herself accordingly, and gave the following history: Mrs. S. T——, residing in Plainfield, N. J., aged fifty-three years, married twenty-two years; sterile; has, as a rule, enjoyed good health, but is subject to tumors. Fifteen years ago she had a large tumor in the abdomen, and was told by reliable physicians that the tumor was a fibroid of the uterus. An irregular physician treated her by animal magnetism, which consisted in manipulations over the whole body. The tumor disappeared entirely after two years' constant treatment by massage.

Dr. Lefferts, of this city, treated her afterward for a tumor in her throat, and has removed a large papilloma from her vocal cords. Soon afterward she felt a tumor growing in her neck, near the articulations of the clavicles with the sternum. The same magnetic physician who rubbed away the fibroid was employed, and, after long-continued magnetic manipulations, this tumor also disappeared. Soon after she felt a hardness in her left breast. This was one and one-half year ago. As a probable cause for this tumefaction, she recollects distinctly having received, some years ago, a violent bruise, by falling with her breast against the back of a large chair. This hardness defined itself, a year ago, to a distinct small tumor, as large as a walnut, and remained stationary for about six months. During the last half-year it grew more rapidly, and, two months ago, in the centre of the tumor, a hard nodule presented, visibly bulging out, and driving the skin outward, which has here a bluish red color. At the present visit this nodule is four inches from the nipple, and one inch in diameter, of equal size in both directions. It forms a regular circle, and is also the centre of the whole tumor, which is five inches in diameter, forming again an irregular centre, the margins diffusing on its irregularly nodulated borders.

The mammary gland is very large, and greatly developed; the nipple is normal, not invaded by the disease, and about one and one-half inch from the margin of the tumor. The tumor is situated in the left mamma, between the nipple and the axilla, occupying more the upper half of the breast; apparently it is movable, but the deeper parts are probably posteriorly agglutinated to the pectoralis, if not to the ribs. Dr. Stillman told me that the patient has carcinoma of the breast, and that the first row of axillary glands were already involved in the disease. I found the condition correspondingly as described by him. Several physicians have seen the case, and all agree in regard to diagnosis but Dr. F. H. Hamilton, who pronounced it a sarcoma.

The patient complains of a sharp, darting pain, which runs through the tumor and the whole breast, is aggravated during the night, and causes uneasiness and insomnia. She has lost flesh and appetite, and feels that her strength and vitality is giving out.

January 25, 1881.—First electrolysis. The negative

* Presented to the New York Pathological Society.

pole of a galvanic battery was divided in three sections; to each was fastened, by screws, a sharp needle. These needles are small, made of pure platinum, one end spear-shaped and sharp.

The three needles were thrust into the tumor, nearly two inches distant from each other, about two inches deep, so that the point of entrance was occupied by a part of the needle which is insulated, in order to preserve the cutaneous surface and avoid any blister from the action of the electrolysis. The needles were inserted near the outer margin of the tumor, and encircling its circumference. The positive electrode is a large-sized carbon, covered with sponge, and is applied near and outside of the tumor, generally opposite to the negative pole, in order to have the electric current passing through the whole tumor. But as the chemical action of electrolysis is desired from the negative pole only, the positive sponge must always be applied on sound tissue, outside of the affected part. This rule has reference only to *this* method and *this* stage of disease and procedure. When the electric circle is closed, the current is slowly increased, cell by cell, the strength to be regulated by the toleration of the patient, as the application is made without an anæsthetic. In the present instance twelve cells were used for twenty-five minutes, after which the strength of the current was diminished slowly, cell by cell, until zero was reached. During the application, the electrodes of both poles must be held steadily in close proximity to the patient's body, avoiding every interruption or breaking of the current.

The batteries used in this case were the constant galvanic battery made by L. Drescher, the elements consisting of zinc and carbon.

January 26th.—Patient feels better. Since yesterday, after the electrolytic application, all pain has ceased, she has slept well, and feels stronger and in better spirits.

Second electrolysis.—Again three needles were used, as before, at equal distances near the outer margin of the tumor, continuing to form a circle. To-day the patient could endure the current of seventeen cells for twenty-five minutes, sitting on a chair and chatting pleasantly. Of course no anæsthetic was given, and, nevertheless, no pain was felt.

January 27th until February 1st.—External applications of galvanism were given daily. Both electrodes were sponges: the negative applied on the tumor, the positive outside, and moved around the tumor.

February 2d.—Third electrolysis.

February 3d.—Fourth electrolysis.

February 5th.—Fifth electrolysis.

Each time three platinum-needles were used, the current was fifteen to nineteen cells strong, and each seance lasted twenty-five minutes. The average current of toleration was seventeen cells. Until now, fifteen needles in all have been used, which complete a regular circle.

February 7th and 8th.—External galvanization.

February 9th.—Sixth electrolysis.—Three needles are inserted in intermediate spaces, so that the tumor is worked over from beyond the periphery toward the centre, but without touching the cyanotic nodule in the centre. The tumor is now more defined at its edges, a hard, well-marked mass by itself, imbedded and surrounded by normal tissue, soft to the touch.

Before treatment was commenced, the tumor and sound tissue felt like one continuity, without any marked boundaries. Now it appears to be lying loose in this soft flesh, and can be moved. The patient has come daily for treatment from her home in Plainfield, in the most severe weather and blizzards, and, nevertheless, says herself, that her general health has improved. Since the first electrolytic seance, she never has had any pain, has slept well, has a good appetite, and has improved in general health.

February 11th to 20th.—External galvanic applications for about thirty minutes daily.

February 21st.—Seventh electrolysis.—Three needles to the base of the tumor. The needles were introduced below the breast, points of entrance in healthy tissue, and then pushed horizontally beneath and to the base of the tumor. Current was twenty cells strong for fully thirty minutes. Tumor itself is now smaller than when treatment was commenced, the diameter each way only four inches, very hard, defined, lying like an apple imbedded in soft tissue, can be moved about, and nearly lifted up from its base.

February 23d—Eighth electrolysis.—Three needles to the base of the tumor in the same manner as seventh seance, working beneath the other half of the tumor, on the side of the median line of the body. Current of thirty-two cells for thirty-five minutes. Patient felt no pain, and when the needles were removed from the body, it was evident they came from a necrotic mass. During the application a hissing sound was heard, almost like steam escaping from a boiler, caused by the force and chemical action of the electrolysis.

February 24th to March 7th.—Almost daily applications of galvanism externally.

March 9th.—Ninth electrolysis.—Three needles in tumor on left side; thirty-four cells for thirty-five minutes.

Dr. Lefferts has examined the throat, and finds that the papilloma has grown again to such an extent that the larynx is filled up to nine-tenths. This state interferes with the treatment of the breast, as the final destruction of the tumor must be done under anæsthesia, which, under the circumstances, is an impossibility.

March 11th.—Dr. Lefferts has removed a part of the papilloma. Patient is weak from the operation. Tumor of breast is inflamed from the last electrolysis.

March 12th.—Tumor bulges out, getting softer; nodule is dark blue, and looks as though it might burst at any moment.

March 14th.—Nodule has broken, followed by a slight hemorrhage.

March 17th.—Tumor suppurates, nodule sloughs.

March 18th.—Patient came to the office. Nodule is necrotic, sloughing; no sensation. Tumor is inflamed, and increasing in size. Patient's strength is failing.

Entire sloughing-out and suppuration of tumor would last too long, and, under the circumstances, the patient's life may be endangered by asthenia, and even septicæmia. Again, while the upper part sloughs, the disease may spread in the depth of the tumor. For this reason, extirpation was decided upon for the next day.

March 19th.—Operation in Plainfield, with the assistance of Drs. Hund and Probasco. The anæsthetic used was the bichloride of methyl. An elliptical incision, eight inches long, was made below and above the diseased parts of the tumor, so as to include in the removal all affected cutaneous tissue, and even

going beyond it on both sides. Then the tumor was dissected out, mostly with knife and scissors, assisting with the galvano-cautery. The tumor was larger than expected, firmly agglutinated at the base to the deltoid, and extending toward the axilla. After removal, the deltoid was exposed and laid bare. Some of the fascia and muscular fibres of the deltoid looked suspicious, and were removed. The dissection had to be continued into the axilla, from which several affected glands were removed, while the artery could be seen distinctly pulsating. The cavity was touched with the galvano-cautery, which also controlled hemorrhage. The wound was brought together, and closed with silver-wire sutures. A drainage-tube was left in it; adhesive strips were placed between the sutures, while compresses and firm bandages completed the dressings.

It may be stated here, that the extirpation was permitted only under the condition to take out the tumor *only*, and not to disturb the nipple or the other part of the breast, which appeared healthy. This statement explains why the whole gland was not removed.

Patient passed a comfortable night, and slept well after having taken twenty drops of McMunn's elixir.

March 20th.—Patient is comfortable; has no pain; pulse, 76; temperature, 99½° F.

March 21st.—Pulse, 88; temperature, 102°, which was the highest during her illness. Both pulse and temperature fell gradually, so that it was normal on the fifth day.

March 24th.—Half the sutures were removed.

March 27th.—All the remaining wire sutures were removed.

March 28th.—External wound has healed.

March 29th.—Large quantity of laudable pus per drainage-tube; shows under the microscope only the characteristic cells of pus.

April 2d.—Cavity is filling up.

April 5th.—Patient is riding out, and walks out-of-doors.

April 9th. — Drainage-tube removed; opening filled with oakum. General health is very good.

April 30th.—Suppuration has ceased; cavity is all healed up.

May 7th.—A hardening is perceived in the cicatrix, just seven weeks after the excision.

May 27th.—Hardness in cicatrix still there, but has diminished in size, and appears more defined in its boundaries. One spot particularly feels sore on pressure or on stretching. This suspicious hardening is one inch long and half an inch in width, and also one and one-half inch from nipple. Toward and in axilla everything appears to be healthy. Constitution and general health is excellent; good appetite.

June 6th.—The suspicious-looking place in cicatrix is inflamed and more hardened, and there is no doubt that this is a recurrence of the malignant growth.

June 8th.—A blister is raised.

June 13th.—Decided demarcation, spread in a circle, which begins to show signs of suppuration. Poultice ordered.

June 16th.—Upper layers of the circle are dead. Poultice has softened the whole breast, which no longer pains on touch.

June 25.—A neurotic detritus, the edges defined and surrounded by a deep fissure. Outside and around this demarcation the breast is soft and normal; no pain.

July 1st.—No smell; no suppuration; neither has any dead tissue come away. The breast is much inflamed and painful. Poultices continued.

July 9th.—Clipped off, with scissors, a piece of the cicatrix. My friend, Dr. Robinson, examined it under the microscope in my presence. The specimen was fresh and partly necrotic, which interfered with the examination, but malignant cells were found, which prompted the energetic destruction of the growth.

July 13th.—In New York, at my office, electrolysis in the following manner—bichloride of methyl was admistered by Dr. Hund; Dr. G. Meier also assisted: A platinum-needle, connected with the positive pole, was introduced into the centre of the dead mass, while the negative platinum-needle was inserted successively in two hard places beneath and close to the cicatrix. The object now was to destroy the diseased tissue at once, and to let it slough. As the part to be destroyed occupied only a small area, it could be accomplished easily and in a short time, whereas in March the condition was different. The current of electrolysis worked well, but could not be kept up long enough, as the patient, even under the anæsthetic, acted in a nervous and irritable manner. But good work was done, even if it could not be finished. The patient had to go home to Plainfield after the operation, and for this reason also she could not be kept too long under an anæsthetic.

During this operation, particles of the infected cicatrix and some broken-down tissue were clipped off for microscopical examination. Dr. Hund and myself examined these specimens with the microscope, and found carcinoma cells as a proof of the recurrence of the disease in the cicatrix three months after extirpation.

July 19th.—Electrolysis in Plainfield under bichloride of methyl, assisted by Dr. Hund. A zinc-needle at positive pole was inserted in the centre of the dead mass. The negative pole, as a platinum-needle, was introduced successively into different places around and on the edges of the suspected mass, leaving it in one place about five minutes. Of course the needles were inserted, as well as removed, while the battery was at zero. In each place just as many cells were used as were required to either soften the hardened place or to destroy it entirely. The first process is a restoration of tissue by absorption of the diseased parts, while in the second case the malignant part is destroyed because it is past redemption by absorption. A very powerful battery was used, and in each place from twenty to forty cells, according to the state of the tissue; the cicatrix and surrounding parts were well worked over, so that no hard mass was left behind.

July 22d.—Patient had fever on the 20th, and a large inflammation and swelling of parts around the tumor, which is due entirely to the after-effects of the strong current of electrolysis. A large mass of dead tissue was removed without causing any pain. Edges of fissure look healthy, smooth, and clean. Base of wound is normal muscle, and in it spring up good, laudable granulations. Pulse is strong and good, temperature normal. In axilla, and around that region, all appears healthy.

July 28th.—Patient is in good spirits, walks about out-of-doors, and goes out riding. Pulse and temperature are normal. Wound looks well, with healthy granulations filling up from the bottom.

August 1st.—Patient came to New York, feeling better and more lively than at any time since being under treatment. Wound looks healthy; margins begin to fill and heal up; skin-edges looking pink,

with a whitish film of cicatrization. Breast, nipple, all muscles and glands are soft, and no suspicious places can be discovered.

No medicine at all has been given since treatment began.

August 6th.—Axilla does not show the slightest sign of infiltration.

August 20th.—More improvement in every way. Granulations have filled up all cavities, and skin is forming rapidly. Breast is as soft as it can be in a healthy state. Patient is lively, has a good appetite, and enjoys good health in general. No medicines were given.

September 1st.—Patient presented herself in good health, recovered entirely, so that she was declared positively well.

November 23d.—Mrs. T. has remained well, enjoyed excellent health, and her breast looks now normal; even the hollow place from which the tumor was removed, has almost filled up. There is at this time no indication of the recurrence of the disease.*

The specimen I present is the tumor of the breast, extirpated in Plainfield, March 19, 1881, as a cancerous growth. It has been preserved in Wickersheimer's fluid, only too well to show the characteristics as it appeared when removed, so that now it looks more restored to a normal color and general appearance. In cutting through its centre, you will find, as a nucleus, a hard, onion-like mass, presenting the characteristics of a scirrhus. Here you see a broken-down mass and, externally, the nodule spoken of.

Dr. Hund has prepared the microscopical specimens which I submit here for examination: First, we have two sections from the tumor, prepared only yesterday; next, we have two sections prepared from the indurated glands removed from the axilla at the operation, which illustrates the malignity of the tumor, and that the axillary glands were already affected when operated upon. According to many authors this would show that the disease has become constitutional, and thereby incurable.

In a microscopical section were shown *(a)* spindle-shaped cells of sarcoma, with distinct prominent nuclei; *(b)* the same cells degenerating to a scirrhous character, with a gradual diminution in size of these cells; *(c)* formation of alveoli, containing epithelioid cells.

The large, spindle-shaped cells were those of a sarcoma; the smaller cells gave the structure the appearance of scirrhus; and finally, the alveoli containing epithelioid cells indicated the existence of a sarcoma, which degenerated into a true carcinoma. Investigating another section, there was seen nearly the same condition as in the former section, with the exception that the large sarcoma-cells were less distinct, were degenerated cells of a scirrhous character, and with alveoli. The whole structure had the type of a well-defined scirrhus, studded here and there with epithelial cells and alveoli. Both of these sections were prepared eight days after the operation, and at that time were the only proofs; but an additional and indisputable one was obtained seven weeks later by examining a portion of the cicatrix, which was found to be infected by carcinoma. The specimen of cicatrix, which had been worked over by electrolysis, was mortified (most likely from rapid contraction), and, therefore, gave only a dim picture, but, nevertheless, clear enough to prove the recurrence of the disease. We found embryonic indifferent cells, and giant cells of sarcoma, as well as scirrhus.

We found, therefore, elements in these specimens representing different varieties of cancer and sarcoma; and the question arises, if they can exist together in one growth, or if either form can change into the other? At this Society, specimens have been presented, illustrating that cancer may change to sarcoma; and at the same time it has been denied that sarcoma can degenerate into a cancer, for the reason that the latter is more highly organized than the former. But the specimens presented here to-night appear more as if the disease had begun as a sarcoma, and afterward degenerated into a scirrhus.

To sustain this opinion we have good authorities. Rindfleisch* describes the "Sarcoma carcinomatodes," and also says: "The sarcomatous carcinoma represents the second possible combination of carcinoma and sarcoma. The epithelium of a gland degenerates in the same manner as in any soft carcinoma of a gland, at the same time the interstitial connective tissue undergoes sarcomatous degeneration. This combination I would call a carcinoma, because the signs of sarcoma show themselves only in the primary tumor, whereas the recurrence and metastasis appear, as a rule, as a pure, soft, glandular carcinoma." †

This quotation is taken from Rindfleisch's 5th edition, published in 1878.

Rindfleisch has also said, in his lectures at Wurzburg in 1879, that a sarcoma may change to a carcinoma, which is reported to me from personal notes by Drs. Buechler and Jacobus. We next quote Billroth ‡ as follows: "Sarcoma is a tumor, consisting of tissue belonging to the developmental series of connective-tissue substances (skin, cartilage, bones, muscles and nerves), which, as a rule, does not enter into the formation of a perfect tissue, but tends to peculiar degenerations of developmental forms;" and his prognosis is that, if sarcoma first appears at between thirty and forty years of age, we have to fear general sarcomatous infection, or *actual transformation to carcinoma by epithelial proliferation.*

---

THE TREATMENT OF PHTHISIS BY ANTISEPTIC INHALATIONS is now being quite extensively discussed. The value of this method was first systematically studied four years ago by Dr. G. G. Sinclair Coghill, of Ventnor, England. The practice of using antiseptic respirators is no longer a novelty in England. Additional evidence as to the value of the respirator has recently been given by Dr. Batterbury in the *British Medical Journal.* A new form of skeleton respirator has been invented by Dr. E. MacDowel Cosgrave.

PRACTICAL AMALGAMATION.—The following advertisement copied from an exchange reminds us of the nursery ballad, "Jack Spratt could eat no fat, his wife could eat no lean," etc.:

"WANTED.—A fine-looking, unmarried homœopathic physician, who understands the eye and ear specialty, to join an allopathic specialist in a town where homœopathy is well introduced. Address," etc.

Evidently the millennium is at hand.

---

* The specimens, consisting of the extirpated mammary tumor, and parts of the cicatrix in which the growth returned, were presented to the Pathological Society, New York, November 23, 1881, together with microscopical sections from tumor, axillary glands, and cicatrix, illustrated by drawings.

## ACUTE DIABETES MELLITUS.

By GEORGE T. WELCH, M.D.,

KEYPORT, N. J.

Dr. George Harley states in his work on the urine and its derangements, that "there are such things as *acute*, as well as *intermittent diabetes*," and quotes briefly from a report made by Dr. Noble in the *British Medical Journal*, January 17, 1863, of two cases of the former: one, a boy of seventeen years of age, who died three days after the disease was discovered, and only a few weeks after he first felt ill; the other, a young lady, who died on the tenth day after the nature of her malady had been diagnosed.

Dr. Brunton, in Reynolds' "System of Medicine," says: "Cases have been recorded in which the disease seemed to run a course of only a few weeks before phthisis set in," but Dr. Noble's report is the only one I can now find in several treatises on diabetes mellitus, where the disease ran its course with such shocking celerity. This being so, it must be of interest to the profession to hear one other detailed, which came under my notice last Thursday, and terminated fatally within sixty hours.

M. C——, a young man thirty-two years of age, tall and stout, weighing in health 240 lbs., came to my office for treatment on the afternoon of December 8th, complaining of what he called malaria, and for which he said he had taken quinine without benefit. He was then in a state of exhaustion, with a tongue dry and irritant as a rasp, and tortured by fiercest thirst. Upon inquiry, I learned his health had been excellent to within three weeks, when, without apparent cause, he began to pass enormous quantities of urine, and consume an extraordinary amount of liquid. He had lost 25 lbs. in weight in about fifteen days. His appetite had not failed him until two days before, when the bowels had been moved copiously, after taking repeated cathartic doses to overcome an obstinate constipation, since which time he had lost all desire for food, and felt more than usually wretched. His breath had an odor of hay. He stated that, when voiding urine, if a drop should fall upon his boot or clothing it would leave a white spot, and showed me several recent spots on a corner of his overcoat.

I found the urine to have a specific gravity of 1040, and with the copper test to show a large amount of sugar. Examined since, under the microscope, abundant crystals of diabetic sugar have been exhibited.

My patient called at the office on Friday, but was now in an almost incoherent condition, skin hot and dry, heart laboring hard, nausea, constipation, excessive diuresis. He told me he had probably passed twenty pints of urine, as nearly as he could estimate, during the past twenty-four hours. I directed him to return home at once and remain there, continuing the prescribed treatment, with supporting measures added, when I would call and see him the next morning.

During the night he ate ravenously of ice, and, ascertained by subsequent measurement, passed about a pint of urine every hour until 3 A.M., when, being hastily summoned, I found him vomiting, breathing heavily between whiles, sighing, and in great apprehension of mind. He complained of gastric pain, probably caused by the ice, which, with the vomiting, was soon ameliorated. Calling again at 9 A.M., I found he had taken hourly doses of medicine, and in answer to my questions stated he felt better. No more urine had been passed.

At 2 P.M. Drs. Arrowsmith and Hodgson met me in consultation. The patient was in profound coma when we reached the house, and died in that condition at 3 A.M., on Sunday the 11th inst., sixty hours after his disease was first diagnosed.

His system did not respond to galvanism, revulsives, or hypodermic measures after coma began. I introduced a catheter into the bladder, but drew off only about eight ounces of urine, and a subsequent use of the catheter some hours afterward did not bring so much.

Any intelligent physician will see that, in a case sliding so rapidly into the grave, scarcely any of the remedies appropriate to saccharine diabetes could be used. The appetite being gone entirely, it was useless to speak of dietetic measures, and beyond tonics, acids, and supporting measures, there was scarcely time to look about one before life had hurried away.

No autopsy was obtainable.

## THE SUCCESSFUL REMOVAL OF A SUB-PERITONEAL FIBROID OF THE UTERUS, WITH REMARKS.

By R. B. HANAHAN, M.D.,

WINNSBORO, S. C.]

It is with mingled feelings of regret and satisfaction that I offer the following case for publication—regret that I have to publish my errors in diagnosis, and satisfaction in knowing that, despite those errors, the result has been satisfactory and happy, and I believe that I have been instrumental in rescuing from death one whose fate was sealed.

On the 25th February, 1881, I was called to see Hannah J——, a colored woman, living about five miles from Winnsboro, S. C. I found her abdomen enormously distended, some slight anasarca of the lower extremities, bowels constipated, tongue heavily coated, conjunctiva discolored, urine scanty and high-colored, and her skin harsh and dry. I was disposed to believe it a case of ascites from derangement of the liver, but came to no positive diagnosis. Upon my second visit I accidentally happened to meet with the former owner of the woman, and she inquired if Hannah had informed me of a tumor growing in her side. That gave me a new departure, and on my next visit I ascertained that the tumor was still there, and had grown considerably since her illness. Upon examination externally, I could indistinctly trace the outlines of the tumor, located, as I thought, in the right iliac region, but could find no evidence of its presence upon indagation. I introduced the sound, but still could trace no connection between the uterus and tumor, as shown by motion, etc. I arrived at the conclusion that here was a case of ovarian tumor, and possibly my conclusion was hastened by a desire for an operation of that kind. However, I obtained the advice and assistance of an older practitioner than myself, and we agreed to tap the tumor, when we could form a more accurate opinion. This we did, and drew off about three and one-half gallons of water. We could then distinctly trace the outlines of the tumor, and our former diagnosis was confirmed. We introduced the sound again, and still could detect no motion in the tumor, nor anything to cause us to doubt the correctness of our previous

conclusions. I determined to operate, and selected a day not far distant, for the woman was going down and had reached the point stated by Dr. Emmet to be the one for proceeding, viz., a shrinking of the fat about the muscles of the neck and disturbance of the digestive system. I examined the urine and could find no kidney degeneration; so I directed a warm footbath every night, the skin to be rubbed with vaseline, a generous diet, and her bowels to be attended to. I had hoped that the anasarca would have subsided after the pressure was taken off the renal vessels by the tapping, but at the time appointed I could perceive no difference.

The woman being exceedingly anxious for the operation and the surrounding circumstances about as favorable as I was ever likely to have in a darkey, I determined to perform it. On Sunday, the 29th of May, assisted by Drs. Robertson, Aiken, Madden, Scruggs, and McMaster, I chloroformed the woman and proceeded with the operation. Upon cutting through the abdominal parietes, I found instead of a healthy and shining peritoneum, a dark and congested membrane, so different from what I expected to meet as to create a doubt whether I had reached the peritoneum. Picking it up, however, and making a slight incision the water gushed forth and I then thought it was the cyst I had divided. Upon the stoppage of the flow of water and dividing upon a director the membrane, to my consternation and surprise a fibroid tumor presented itself at the opening, and the next question was, abandon the operation or remove it? Passing a sound around the tumor and finding no adhesions, and that it was pedunculated, I cut through the pedicle, taking the precaution of keeping the edge of the knife near to the tumor, in fact I may say making the incision through its base. There were two arteries supplying the fibroid, neither of which did we secure, they retracting so quickly. The hemorrhage was frightful, and not anticipating any such contingency, I was not provided with a cauterizing iron. We could see no termination except death. I found, however, by keeping a sponge firmly pressed upon the site of the arteries that the hemorrhage was controlled. I then proceeded to close the abdominal wound, adopting the method recommended by Dr. Emmet of passing the needle at least an inch from the edge in the peritoneum, and bringing it out nearer to the edge in the skin. After passing the sutures (I used silver wire) I removed the sponge and found there was still some hemorrhage, so it was decided to use a preparation of iron, which was freely done. A sponge was saturated with the solution of persulphate of iron and passed around in the wound, and as death was what we expected, we were not over particular as to what and where it touched. The abdominal wound was then closed, leaving an opening at its lowest point for drainage.

At my visit in the morning, about 10 o'clock, I fully expected to find some discharge issuing from the wound, and had provided myself with syringe and means to wash out the cavity. To my surprise, on attempting to pass a gum catheter through the opening I had left I found union had taken place, and the wound closed through its whole extent. The pulse was 120, thermometer 100°. She had reacted entirely and promptly from the chloroform, her skin and kidneys were acting profusely, which they had not done for months. She was cheerful and in good spirits, and seemed to be doing well. The pulse fluctuated between 88 and 100 for a week, and the thermometer ranged about 100°, but she never suffered in any way, and the quickness of pulse seemed rather the result of debility than from any fever that might be present. Her skin and kidneys continued to act freely, and on the eighth day, when the sutures were removed, there was no sign of anasarca. The wound was entirely healed, except a small spot about an inch below the umbilicus, which has since healed up. The woman's appetite had returned, and there were no untoward symptoms. In two weeks she was sitting up, and in less than three weeks she was walking around the house. I carried out as fully as possible the Listerian method. I had devised an atomizer, but from accident it would not work; in every other respect it was fully carried out. Upon the removal of the tumor we discovered two others. One, a small one, on the left anterior surface, and a larger one on the posterior surface of the uterus. The weight of the tumor removed was 29 oz. 7 dr. I desire to call particular attention to the fact that there were no ligatures used, no opiates at any time, and no stimulants, except a little just prior to the administration of the chloroform.

If the confession of my errors enables any professional brother to avoid similar ones, or if by the publication of this case I have contributed anything to the literature of the subject, then my purpose has been fulfilled.

## Progress of Medical Science.

THE DETERIORATION OF THE ATMOSPHERE IN MINES CAUSED BY THE EXPLOSION OF NITRO-GLYCERINE PREPARATIONS.—Of late, says Mr. Colquhoun (*Aust. Med. Journal*, June, 1881), it has become noticeable that miners are disposed to attribute much of the illness from which they suffer to the influence of the "fumes" resulting from the combustion of nitroglycerine preparations. Mingled with these fumes, very probably, is unexploded nitro-glycerine. One symptom which seems to be always experienced is a throbbing sensation in the temples and forehead; in many instances there is a slight feeling of nausea, and a transitory faintness. These manifestations gradually abate as the air grows clear. After a time the immediate effect is felt less acutely, although there is no real tolerance established. It is difficult to determine whether a permanent deterioration of health is brought about on account of the operation of various other causes of disease. The author has seen several instances in which precordial pain, dependent upon organic cardiac lesion, was exacerbated by the inhalation of the dynamite fumes. Without more extended observation it would be difficult to say that cases of this kind are particularly common among miners, but it is important at least to determine whether anything in their surroundings is calculated to aggravate special forms of disease, if it does not directly induce them. Nitroglycerine is therapeutically an antispasmodic; where spasm does not exist its action is chiefly to weaken the muscular power of the heart. Although this weakening might not reveal itself for a long time by physical signs, yet there would be present the general and functional debility accompanying feeble cardiac action, together with throbbing in the head. Miners may be expected to be more powerfully affected on account of the operation of various other depressing influences. By their occupation they are particularly predisposed to pulmonary diseases,

and the action of a cardiac depressant like nitroglycerine is likely to influence and be influenced by any pre-existing lung affection. There are two other potent causes of ill-health dependent on the condition of the atmosphere in mines; an undue amount of carbonic acid, and the suspension of fine dust in the air. Means to secure perfect combustion of the nitro-glycerine, and better ventilation, are indicated.

Ovariotomy during Pregnancy.—What shall be done with a simple ovarian cyst, or a compound ovarian tumor (solid and fluid), coexisting with pregnancy, are questions discussed by Dr. Wilson in his paper reprinted from vol. v. of the "Gynecological Transactions," 1881. In the case of an entirely cystic ovarian tumor, the author advises removal in preference to repeated tappings, as he also does in cases of compound tumor whose adhesions are not extensive and firm, and where the fluid largely predominates. In tumors, either solid, semi-solid, or both, and so large as to impede the growth of the uterus, Dr. Wilson would prefer ovariotomy to the induction of premature labor. The important element in prognosis in cases of ovarian tumor coexistent with pregnancy is the extent of adhesions to adjacent parts, not whether the tumor is solid or fluid. From what the author says it will then be seen that he holds, where pregnancy supervenes on an ovarian tumor so large as to endanger the life of the mother before she can reach to term, it is better to perform ovariotomy within the first three or four months after conception, than to tap or use other temporizing means in the effort of carrying her to term. Tapping he objects to, because each operation of this kind is followed by new and stronger adhesions to neighboring organs, and each adhesion adds to the danger of a subsequent ovariotomy. The statistics of ovariotomy during pregnancy show excellent results for both mother and child (deaths, five women and nine children; saved, twenty-four women and twenty children). Dr. Wilson thinks that with modern operative improvements, etc., the number of deaths of mothers might have been reduced to three. Statistics also seem to show that ovariotomy in pregnant women, previous to the sixth month, is more successful for the mother, and vastly more successful for the child than the same operation at a later period.

Laparotomy and Cystorrhaphy in Perforating Intraperitoneal Wounds of the Bladder.—As deductions of a recent series of experiments upon rabbits, whose peritoneum is reputed to be particularly sensitive, Dr. Vincent presents the following conclusions:

Contact of urine with the peritoneum is not as fatal as has been supposed, since, of fifteen rabbits, twelve have survived a momentary or prolonged urinary inundation.

The peritoneal surfaces being placed in juxtaposition, the vesical suture, composed of independent metallic loops left in the abdomen, may be employed with almost a certainty of success.

In intraperitoneal solutions of continuity of the bladder, followed by an extravasation of urine into the peritoneal cavity, vesical suture, preceded by laparotomy, and executed immediately or after a short space of time, will almost certainly save the subject; this it will do, whatever be the cause of the lesion, and in spite of grave complications.

When intraperitoneal perforation of the bladder has been executed and extravasation of urine taken place, the subject may still be saved, although laparotomy and suture be deferred for from three to forty-eight hours.

The possibility of spontaneous cicatrization of vesical perforation has been experimentally demonstrated in animals with a sensitive peritoneum; but it is not the rule.

In view of the foregoing conclusions, and the mortality in intraperitoneal perforations in man, the author in such cases recommends laparotomy and vesical suture; these must be rapidly executed. His experiments, furthermore, argue in favor of the supra-pubic operation for stones of large size and extreme hardness, small and friable calculi being removed by the lithotrite. In his operations upon animals, he exposed the intestines as little as possible, and extracted the bladder through a very small opening. He objects strongly to the use of the spray, and the washing out of the peritoneal cavity with the carbolized solution, but advises a scrupulous observance of other customary antiseptic measures; he also recommends that the room be disinfected with a strong spray of carbolic acid several hours before the operation.—*Lyon Medical*, September 25, 1881.

Influence of Pneumo-Hydrothorax upon the Course of Pulmonary Tuberculosis.—Dr. Paul Meusnier, of Blois, communicates to the *Gazette des Hôpitaux* (September 24, 1881) a case of pulmonary tuberculosis, the progress of which he considers to have been retarded by the supervention of pneumo-hydrothorax. This fortunate result he attributes to the compression of the diseased lung, by which suppuration was limited and septic poisoning prevented. The following is a *résumé* of the case: In July, 1879, Dr. M. first saw the patient, a young man of twenty years, who had had phthisis a year. The disease was confined to the left lung, and had advanced to the stage of excavation. The general condition was bad, the cough incessant, and the expectoration purulent. Emaciation was extreme. A daily hectic paroxysm occurred. No change took place in the symptoms until September 27th, when perforation of the lung occurred and pneumo-hydrothorax was developed. After the disappearance of the dyspnœa and pain incident to the perforation of the lung, marked amelioration of all the symptoms was manifested. The cough and fever disappeared, and the general health improved. The patient gained three kilogrammes (six and a half pounds) every two weeks, and in February weighed more than ever before in his life. Improvement continued until May, 1880, when, after exposure, the pleuritic effusion greatly increased. On June 8th thoracentesis was performed, and two litres (three and a half pints) of pure serum withdrawn. The fluid reaccumulated, and assumed a purulent character. Septic fever now reappeared, and the patient died suddenly, before thoracentesis could be again resorted to.

Cretinoid Œdema or Myxœdema.—The *Gazette des Hôpitaux* (September 24, 1881) attributes priority in the discovery of the so-called myxœdema to Dr. Morvan, of Lanniles. He is said to have reported fifteen undoubted cases of this disease in 1875, before the publication of any cases by Charcot or by English writers. His cases were characterized by anasarca, particularly well marked about the face, the legs, and the wrists, and by general paresis without muscular atrophy or impairment of the mental powers. Although the muscular paresis was

marked, it did not incapacitate the patients from walking. The movements of all the limbs were well co-ordinated, but very deliberate; cold seemed to notably aggravate the disease. The speech was slow and hesitating, the tongue was moved with difficulty, the voice was hoarse, the fingers lost their flexibility; the extensors were more deeply involved than the flexors. The slightest exertion caused great fatigue. Paresis of the muscles of the tongue and larynx, coupled with the œdema, serve to explain the symptoms referable to these organs. The paresis involved the organs of vegetative life in certain cases. Thus, the cardiac action was sometimes retarded, and the frequency of the respiratory movements diminished. Sensation was unimpaired in all the cases, and hyperæsthesia was even observed in some of them. Amblyopia, delirium, hallucinations, and vertigo were occasionally present, but the general health was excellent, the appetite and digestion good, and the urine normal. Women were almost exclusively attacked. The type of the disease was milder than that of the cases observed by Charcot and in England, presenting neither the cretinoid cachexia nor the œdema of the mouth, larynx, digestive organs, and urinary tract, described by Charcot, Gull, and Ord. M. Morvan regards cold as the chief exciting cause, and menstruation, repeated pregnancies, and prolonged lactation as the predisposing causes of the disease. Middle-aged women are most frequently affected. No cases are cured, but in none is the disease directly mortal. No efficacious remedies are known.

Treatment of Sciatica by Hypodermic Injections of Nitrate of Silver.—Dr. Greslon reports (*La France Médicale*, September 29, 1881) the radical cure of a case of sciatica, which had resisted all ordinary methods of treatment, by hypodermic injections of the nitrate of silver. The patient, a lady of fifty three years, was of a gouty and rheumatic diathesis. She had recently suffered from several attacks of acute articular rheumatism. Her metacarpo-phalangeal articulations presented the characteristic deformities of arthritis deformans. In March, 1878, the patient was attacked by sciatica in the left thigh and leg. The most severe pain was experienced in the calf and at the sacro-sciatic foramen. After unsuccessfully treating the case for twelve days with sinapisms, vesicatories, and anodynes, Dr. G. injected five drops of a twenty-five per cent. solution of nitrate of silver into the deeper tissues of the calf, at the most painful part. The injection was attended by violent pain, and followed by the formation of an abscess, which was opened at the end of a week. A few days later the neuralgic pains had completely ceased in the leg. Eight drops of the same solution were then injected over the sacro-sciatic foramen. No abscess ensued, but an inflammatory exudation occurred, and discharged, six days after the puncture, some sero-sanguinolent matter. A week later all pain had disappeared from the limb. The patient has had no relapse of the sciatica, although three years have elapsed since the attack in question.

Paralysis Agitans and Senile Trembling—Static Electricity in Hysteria.—A *résumé* of lectures by Prof. Charcot, delivered at the Salpêtrière, on the above subjects, is published in the *Journal de Médecine et de Chirurgie pratiques*, October, 1881. Prof. C. dwells particularly upon the characteristic symptoms of paralysis agitans other than the tremors, which latter may often be completely absent. He alludes to the peculiar attitude of the patient, whose body is bent forward, while his neck is rigid and his head almost immovable. This rigidity is due to a constant muscular contracture, which affects the flexors first, and always to a more marked degree than the extensors. The facial expression, described as that of surprise, is referred to a contracture of the occipito-frontalis and of the orbicularis palpebrarum. The contracture of the ocular muscles imparts a staring look to the eyes. A similar interference with the function of the laryngeal muscles produces an impairment of speech, which may be interrupted or stammering. The muscular rigidity sometimes causes deformities resembling those of chronic rheumatism, but distinguished by the absence of arthritic swelling, rigidity, and crepitation. The patients experience an indescribable *malaise*, which impels them to incessantly change their position. This abnormal sensation is most marked at night. Although the temperature of the patients remains normal, they suffer from a subjective feeling of intense heat, which is particularly felt on the back and in the epigastrium.

M. Charcot emphasizes the fact that true senile trembling is a rare affection. He asserts that most of the cases of tremor designated by this name were really developed at an earlier age. Senile trembling often localizes itself in isolated muscular groups, causing inco-ordination in the movements of the head and of the extremities. No treatment is efficacious in these diseases.

The same observer has attained remarkable results in the treatment of hysteria by means of static electricity. His apparatus is essentially such a static machine as is used in physical laboratories, although somewhat modified. The patients are placed upon isolated stools, connected with the conductor, and thus subjected to the uninterrupted action of electric currents, which, escaping from prominent points of their bodies, produce prickling and tingling. The appetite is increased and the cutaneous functions stimulated. Special dischargers are provided for the excitation of individual organs, particularly those of special sense. Hysterical contractions, hemianæsthesia, and achromatopsy were completely relieved by the electric bath. Anæsthesia is often permanently, but sometimes only temporarily removed. On the whole, Prof. C. believes static electricity to be more efficacious than the other forms of electricity in restoring the sensibility of anæsthetic parts, and in diminishing the tendency to attacks of hysterical anæsthesia.

Therapeutical Uses of Yerba Santa.—Dr. Salomon reports that yerba santa, or eriodyction Californicum, has in his hands, proved to be a remedy of value in bronchorrhœa, in acute bronchitis, in the cough of measles, and as a prophylactic against laryngismus stridulus. Dr. Salomon employed the fluid extract of the leaves, in doses of ten minims to one drachm, glycerine being the best vehicle, as water and syrups precipitate the gummy portion of the preparation. The author thinks the remedy acts specifically on the mucuous membranes of the air passages as an astringent. In chronic bronchitis he was compelled, in the majority of cases, to abandon its use, and administer other remedies.—*N. O. Med. and Surg. Jour.*, November, 1881.

Woman's Hospital in Baltimore.—It is reported that a movement is on foot to establish a Woman's Hospital in Baltimore.

## THE MENTAL CONDITION OF GUITEAU.

WHATEVER be the view one takes of Guiteau's mental condition, it must be admitted that it is a most complex one, and is deserving of careful study. Furthermore, there never was a criminal the materials for the analysis of whose character are more abundant. We know his history from the very beginning. Guiteau's father was a man of narrow mind and extremely positive convictions. His mother was not a strong, healthy woman physically. The son was born with a brain and nervous system that could be easily thrown out of balance. Under proper training, Guiteau might have made a respectable, though never a very estimable man. There was an innate lack of moral strength and sensibility. His early surroundings and education were calculated to develop the worst side of him. He showed, when a young man, an impressionable and emotional nature; his will was weak, his intellect bright, but only so within a narrow range. He was educated, yet he learned nothing of value, and is even now a very ignorant man. He did nothing to enlarge his intelligence, discipline his will, or correct his judgment. In men of narrow mind and strong feeling there is the strongest tendency to become essentially egotists. Man's natural self-love, when not guided by a broad intelligence or a true morality, continually increases. When these safeguards are destroyed or blunted, as in the insane or criminal, egotism becomes almost supreme. The thoughts of the madman and of the villain revolve about himself alone.

But the egotism of insanity is not so often offensive as it is absurd or curious. And Guiteau's self-concern has always, we believe, stopped short of madness. It was in a large degree calculating and methodical. His schemes were extravagant, but not ridiculous.

Guiteau has never had the *full* capacity to judge between right and wrong. He is like a man born with imperfect hearing. By proper training and self-control he might have learned to do right. But, as a man may destroy, instead of cultivating, a defective sense, so Guiteau finally lost, or nearly so, his capacity for feeling shame or appreciating what is right.

Guiteau was always dreaming of becoming notorious. Every one builds some air-castles. But who can ever conceive how many fantastic projects grew up in Guiteau's mind, out of his egotism and ignorance. To be a great editor, a great theologian, and a great politician—to be something which should make people talk about him—this was always in his mind. Every one has a touch of such ambitions. They show, not insanity, but lack of self-control.

Conceive now such a man, haunted by ambitious fancies, thrust into the political situation of last spring. A way out of the troubles that will, at the same time, gratify his life-long dreams, presents itself. He shakes off the idea at first. But he has not been kindly treated by some of these great officials. He is rebuffed by Blaine, snubbed by Logan, and ignored at the White House. The way by which he can more than get even with these men again recurs to him. Here is an opportunity to be, as he once thought of being, a second Wilkes Booth. There is a fascination in the idea of thus committing a great murder. Every criminal must feel something of this when he has fully determined on his deed. It draws him on like a serpent's eye. Perhaps some vague sense of fatality or "inspiration" becomes mingled with it.

Guiteau's moral sense was too dull by nature and by abuse to revolt at his project. Yet he hesitated. Once he went to the church to shoot, but did not. Again he went to the depot with the same intent: this time, too, he restrained himself.

If Guiteau had not debauched his moral sense and surfeited his vanity by constant self-indulgence, he could never have felt his "inspiration." The vicious longing for the immortality of a Booth, the surliness of a rebuked self-esteem, are vastly more prominent in his history than are the symptoms of "religious monomania." If Guiteau's mental traits are such as to class him among the insane and irresponsible, then let us, for the benefit of society, reconstruct psychiatry. It is not so much that his punishment would deter the weak-minded and insane from criminality. But a failure to punish him would be a stimulus to those criminals who are not insane, but are near enough that condition to feel that they need only act extravagantly in order to be passed off as cases of "primary monomania."

### HOSPITAL SATURDAY AND SUNDAY.

THE public will be specially reminded to-day and to-morrow of their obligations to the sick poor. Hospital Saturday and Sunday come at a time of the year when the human heart is softened by charity and

when alms-giving is a matter of conscience, and substantial remembrances are appreciated privileges. After all that has been said concerning the needs of our large hospitals for more pecuniary support, it would seem a work of supererogation to urge the necessity of large contributions for the purpose. In no better direction can charity flow than in the proper care of the poor and helpless in our hospital wards; and in no surer way can the greatest amount of good be guaranteed for the outlays made. The pecuniary management of our larger hospitals may be considered above reproach. To such as have studied carefully the reports of the Hospital Committee it is a matter of surprise that so much can be accomplished out of comparatively so little. When the average expenses of a patient are reduced to the low figure of one dollar and fifteen cents per day, and he, as poor as any pauper that falls by the wayside, can secure the best available medical talent, the best nursing, the best medicines, and the best nourishment for such a sum, the public can scarcely ask a better object for benevolence. But these facts need only be mentioned to have their significance properly appreciated by such as at this festal season desire to do their Master's work. The statements which have been made concerning the work of the hospitals, in soliciting pecuniary aid from the public at large, has tended in no small degree to elevate these institutions in popular esteem and to break down those prejudices which have been so deeply rooted in the minds of such as are proper subjects of hospital care. It has been demonstrated by facts and figures that neither race nor religion interferes with the practice of the broadest humanity. If one thing more than another entitles a patient to the most skilful treatment and loving care which the best equipped hospital can bestow, it is the fact that the suffering one is the poorest, neediest pauper that can be found. The ever-ready ambulance on its errand of mercy has no time for inquiry into the religion or nationality of the suffering wayfarer; it is enough that he be a stranger, sick or injured, and he is tenderly cared for as the "least of those" who are always with us. It is the exemplification in its largest sense of that liberal Christianity which proves the true aims of pure and practical charity. The better this noble system of caring for the sick poor is understood the more will the tendency be to centralize the necessary help in the required direction for doing the most good to such as are in the direst need. Opportunities will thus be afforded of systematizing much of the almsgiving which has heretofore been indiscriminate in character and consequently barren of good results. It is not too much to expect that an organization, such as that now being perfected by the Hospital Committee, will, with proper encouragement, tend to the suppression of professional pauperism and to the correction of the thousand and one abuses of medical charity with which, alas! the medical man has of late become so well acquainted. From these points of view the profession, always willing to help the suffering and needy, will stand ready to second the efforts of the committee in their noble and disinterested labors, and will use its influence with the public to make the scheme a far-reaching and successful one. From present indications the contributions are destined to be larger than at previous periods; and this is as it should be, not only considering the increasing popularity of the movement but the yearly increase of such as are the fit subjects of hospital treatment.

### PREVENTING CONTAGION IN SCHOOLS.

It is well known that the Board of Education has instructed school teachers to demand certificates signed by the Health Department from children who have been ill from contagious diseases before they are admitted to the schools. The certificate system is an admirable one as far as it goes, but there seems to be considerable difficulty in the way of properly carrying it out. The health authorities, it appears, are unequal to the task imposed upon them, it being obviously impossible, with the present force of inspectors, to grant the number of permits required. Consequently, it is suggested that the certificate of any reputable physician that the child is properly disinfected will answer the purpose. Certainly any qualified physician is competent to do this, but whether he will or no is a question of considerable practical interest. If the giving of a certificate implies, as it should, the actual superintendence of the processes of disinfection by the physician, then very few of such documents can be conscientiously issued. The medical attendant cannot be expected on general principles to give up his time to such duties. If he chooses to grant a certificate in any given case, he may, but to expect it of him as a rule is somewhat presumptuous on the part of the health authorities. It is certainly to be regretted that the Health Board is unable to perform its duties in this respect, but that is hardly a sufficient reason why, even in the laudable cause of protecting the school children, the medical profession should be saddled with any extra obligations. There is no argument against protecting our school children from contagion, but the duty of so doing belongs to the Health Board. The latter board some years ago virtually said that sanitary supervision of public schools was unnecessary, as such work could be easily done by its inspectors. Now it seems that a contrary opinion prevails. The Board of Education, for reasons of its own, which have never borne discussion, has year after year opposed a proper sanitary supervision of schools by officers specially and exclusively appointed for the purpose, and, by way of

dodging the issue, has thrown some extra work upon the health authorities. The latter confess that they are unable to perform the duties, and suggest that they be transferred to the obliging family physician. But behind it all there can be seen one of the most powerful arguments for the special sanitary supervision of our public schools that has yet been offered.

---

IGNITION OF ETHER AT AN OPERATION.

At a clinic held recently by Professor Briggs, at the University of Nashville, Tenn., and during the etherization of a patient for the removal of a glandular tumor of the parotid, the vapor caught fire from the flame of the alcohol lamp of the spray-producer, and the clothes of the patient were ignited. Fortunately neither the patient nor attendants were injured, the flames having been speedily extinguished by the operator. Taking into account the number of times it is necessary to administer ether in more or less close proximity to the flame of a lamp, it is somewhat remarkable that accidents such as the one referred to do not occur oftener. In the great majority of cases accident is prevented by the extra precautions taken by administrators of the anæsthetic. Certain it is that the inflammable character of ether is well known to surgeons and the danger of igniting its vapor hardly needs to be accentuated in commenting upon Professor Briggs' case. In this particular instance most of the conditions favorable to the result were present. "The spray-producer was held at the usual distance from the ether-inhaler, slightly below its level, and there was no draught of wind." The patient had been inhaling the ether for some time and the whole surroundings were saturated with the vapor. The vapor of ether being so much heavier than air, is quite likely to be ignited by any flame at a low level. And there is apparently nothing more or less to be said of this case.

---

THE INSPECTION OF THE THEATRES.

During the past week the chiefs of the fire battalions have been inspecting the various theatres with the view of ascertaining the necessary precautions that are taken against fire, and also for the purpose of suggesting additional means of safety. Although it has been shown that in many instances there is a laudable intent on the part of managers to guard against accident, there is still room for a great deal of improvement in the existing arrangements. For instance, it has been ascertained that in some of the places of amusement, although an iron curtain is provided, the proscenium arch which supports it is made of the lightest wood-work, affording the poorest possible barrier against fire. In fact, in the occurrence of the latter, no surer means of allowing the flames the freest possible course to the galleries could be adopted. Then, also, there are, in many instances, more or less direct communications between the upper part of the stage and the open, inflammable structures of the ceilings and domes. An inspection of the apartments under some of these so-called amusement palaces disclosed the existence of dry rubbish in dangerous proximity to the furnaces and gas-jets. Altogether there is hardly one of the public places of amusement that can be considered absolutely secure in case of a conflagration. This is partly due to the fact that most of these buildings were constructed before the necessities of guarding against the occurrence of fire were sufficiently emphasized, and partly to the impossibility of making many of the required changes without virtually rebuilding the structures. But these are no arguments against the adoption of the most thorough means of obviating future calamities. It is gratifying to learn that the authorities intend to enforce the requisite regulations upon delinquent managers.

---

SPREADING SMALL-POX.

A rather curious fact, illustrating one phase in human depravity, has been brought to the attention of the health office of a village in New Jersey. It appears that a young woman, who had left that locality in consequence of some petty scandal, resolved to be revenged upon her gossiping enemies. While seemingly awaiting an opportunity to this end, her brother became stricken with small pox, in this city, whereupon she caused his transfer to a vacant house in the village aforementioned, since which time she, with her mother, has maintained free intercourse, for several days, with the neighbors and tradesmen in the vicinity. Under ordinary circumstances the case might be considered as one in which the fear of being transported to a pest-house overbalanced every consideration for the safety of the patient or the public. But an altogether different aspect is given it, in view of the expressed threat, on the part of the miserable wretch of a girl, to spread the disease in the village. It is somewhat difficult, even in imagination, to compass the extent of criminality which this case illustrates, and, for the sake of sparing the blushes of ordinary fiends, we trust that the story, as to motives of action, is without foundation. But, aside from this being so or not, the apparent ease with which this case was transferred from this to a suburban locality, in a public hack, which was evidently used by other innocent persons afterward, is a matter for suggestive contemplation by the Health Boards of this and other cities. Doubtless the innocent parties who may expose themselves to the sources of contagion in the vehicle will wonder how they could have caught the disease.

# Reports of Societies.

## NEW YORK PATHOLOGICAL SOCIETY.

*Stated Meeting, November* 23, 1881.

DR. T. E. SATTERTHWAITE, PRESIDENT, IN THE CHAIR.

### ANEURISM OF THE INNOMINATE ARTERY.

DR. EDWARD L. PARTRIDGE presented a specimen with the following history: On the evening of November 9th he visited the patient, and learned that he had been in bed and in the house for that day only. He was hoarse, speaking with difficulty above a whisper, and coughed constantly. His pulse was 90. Temperature normal. His expectoration was quite profuse, muco-purulent, and suggested tracheitis in addition to catarrhal laryngitis. Auscultation of the lungs, without inspection of the chest (as the patient was sweating, and the room chilly), showed slight bronchitis. He attributed his illness partly to exposure, and partly to having talked more than usual at the time of the recent election.

During the last eighteen months he had had slight but frequently repeated attacks of hoarseness, and persistent cough. His wife stated that in his sleep his breathing was noisy. He had observed for some weeks that in the morning, on arising, his face was puffy, the right side being much more swollen than the left. There was no history of syphilis or rheumatism; his age was thirty-four. He passed a restless night.

On the following day, inspection and careful examination of the thorax showed slight bronchial catarrh, involving the right more than the left lung. Some fulness could be observed above the clavicle to the right of the sternum. In and above this situation there was an extensive scar, that seemed to indicate the burrowing of pus which had attended a bullet-wound of the neck received in 1864. Palpation disclosed distinct pulsation of the upper part of the sternum, while the finger, pressed behind or just above the manubrium, appreciated a distinctly expansive pulsation. Percussion showed an area of dulness three and one-half or four inches transversely, and two and one-half inches from above downward bounded by the median line, and above by the clavicle. The heart-sounds were normal. No bruit was present anywhere. Pressure backward above the sternum greatly distressed the patient, producing a sense of suffocation. The radial pulse was weak, but showed no difference in time or force between the two sides.

Pulse was 110, and temperature 101° F. His cough was attended by moderate expectoration, and had no harsh or ringing quality. On the 11th he was much worse. His pulse was 160, temperature 100° F. At times there were slight blueness of the finger-nails and of the face, the right side of which was decidedly swollen, owing to interference with return of venous blood.

On the morning of the 12th his condition was about the same. Dr. Loomis, who saw him then, regarded the condition as aneurism of the innominate, the possibility of a tumor being admitted, but doubted. The interference with the respiratory function was evidently from pressure of the aneurism upon the trachea. The right lung was congested.

Signs of exhaustion were very pronounced. In the evening his pulse was 120, and he was generally easier. His respiration, however, was very difficult and fatiguing to him. Dr. W. T. Bull, who saw him, felt that any operative procedure, which would be necessarily difficult and prolonged, was not worthy of consideration. The use even of an anæsthetic would have been highly dangerous. Death occurred at two A.M., November 13th. The autopsy and removal of the specimen were performed by Dr. Bull.

On removing the skin, superficial fascia, and dividing the sterno-mastoid muscle, the upper portion of the tumor became visible, extending two inches above the sternum, and from the left sterno-clavicular articulation to the junction of the inner and middle thirds of the clavicle on the right side. The specimen was removed *en masse*.

The aneurism involved the innominate artery chiefly. Anteriorly it had produced erosion of the sternum, and the sterno-clavicular articulation was exposed. Posteriorly it pressed against the trachea, the chief point of pressure being at a level with the origin of the right bronchus, the tracheal wall being extremely thin—one-eighth of an inch—and rupture would have certainly taken place at this point within a short time. The aorta was extensively atheromatous from its origin, and somewhat dilated. The heart was not enlarged, the cavity of the left ventricle being slightly dilated. The valves were sufficient, each segment of the aortic valve being fenestrated.

Firm fibrinous layers occupied the upper and anterior parts of the sac.

### EXCESSIVE DILATATION OF AORTIC ORIFICE AND SEMILUNAR VALVES, WITH GREAT ATTENUATION OF THEIR CUSPS, IN A CASE OF ANEURISM OF THE ASCENDING PORTION OF THE ARCH.

DR. E. C. WENDT presented a specimen taken from the body of a man, aged forty-eight, who had died at the St. Francis Hospital. The history was of interest only inasmuch as the symptoms and physical signs had not been sufficiently characteristic to make the diagnosis of aneurism probable during life. A prominent symptom had indeed been the presence of a loud and blowing systolic murmur, most distinctly audible over the base, and projected into the carotids, but this had led merely to the recognition of aortic disease, without establishing the existence of aneurismal dilatation.

At the autopsy, the first thing to attract attention about the heart was the excessive dilatation of the coronary veins, which appeared in some places as thick as a finger.

The left ventricle was much hypertrophied, and greatly dilated. The cusps of the semilunar valves were extremely attenuated, looking as if the least additional strain would have resulted in their rupture. They were also very much stretched, to accommodate themselves to the widened orifice. The cusp immediately above the posterior mitral flap measured two inches at its free border. The adjoining cusps were, however, only an inch long. This inequality of length was a noticeable feature of the case.

The right ventricle appeared as a mere appendix of the left, and the disproportion between the amount of blood that these cavities could hold must have been very great, even during the life of the patient.

As aneurism was not of itself sufficient to lead to hypertrophy of the ventricle, it was probable that the aortic insufficiency had antedated the develop-

ment of the former. Extensive atheromatous changes doubtless were the causative factors of both morbid alterations.

Dr. Wendt also presented a specimen with the following history, furnished by Dr. Haig, House Physician to St. Francis' Hospital:

VALVULITIS DEFORMANS AT THE AORTIC ORIFICE—LOBAR PNEUMONIA—SUDDEN DEATH.

H. L——, aged thirty, native of Germany, a waiter by occupation, was admitted to the St. Francis Hospital, in the service of Dr. Lellman, November 3, 1881. The patient had been addicted to the excessive use of alcoholic drinks for many years. He had an attack of articular rheumatism, which confined him to his bed for two months, about three years ago. Ever since that time he was subject to dyspnœa on exertion, and occasional attacks of spontaneous palpitation. Otherwise he was in robust health, being a man of exceptionally powerful physique—almost an athlete in build. Five days before admission he was seized with a severe chill, and soon developed the symptoms of a croupous pneumonia affecting the lower lobes of the left lung. The physical signs were especially marked posteriorly. At midnight, on the evening of his admission, his temperature was 104°, his pulse 110, and his respiration 40. A loud, long-drawn systolic murmur was distinctly audible over the apex of the heart, but the cardiac rhythm did not appear to be disturbed. The pulse remained of poor quality, however, in spite of appropriate treatment.

On the following morning the patient's temperature had fallen to 101, and he appeared to be quietly sleeping. Later on, in the course of that day, on attempting to give him some stimulants, a peculiar expression of his countenance attracted the attention of the attendants, and a few minutes later he abruptly fell back in his bed, and died in sudden collapse.

An autopsy was made on the following day by Dr. Wendt. The organs in the abdominal cavity showed only the ordinary changes referable to venous congestion. In the chest the lower lobes of the left lung were found to be in the gray hepatization stage of croupous pneumonia. But the disease did not extend to the anterior surface, being most marked behind.

The heart was greatly hypertrophied in its left ventricle, but only slightly dilated. The aortic valves were found to be transformed into a rough, misshapen ring of rigid tissue, containing calcareous deposits. Individual cusps could not be differentiated one from the other. Between their remnants there existed only a narrow slit, barely admitting the tip of the little finger. The other valves appeared normal.

Dr. Wendt thought the case interesting, because it again forcibly illustrated the danger of sudden death from some intercurrent disease in chronic valvular lesions, even when marked disturbances of compensation had given no premonition of impending peril. Of course, cases of sudden death, especially in aortic mischief, were not very uncommon, and might occur even without any interourrent disease.

The generally accepted explanation of such an occurrence was over-distention of the left ventricle, leading to speedy cardiac paralysis. Such an interpretation would hardly cover this case. He thought that the sudden disturbance of a previously fair regulated compensation was directly owing to the pneumonia, which, though not extensive, had nevertheless taken the system by surprise as it were, and thus brought about a rapidly fatal termination.

Finally, he wished to say a word about the use of the term "*valvulitis deformans.*" He was not aware that it had been previously employed, and, although word-coining was a rather reprehensible practice in medicine, yet this compound seemed to him an eminently proper one. It was a concise anatomical expression, indicating a localized lesion. It might appropriately be used for all endocarditic processes involving or confined to the valves, and producing a real deformity in their shape, as was the case in the present instance.

CHRONIC PERIMETRITIS AND VAGINITIS, WITH PURULENT VESICAL CATARRH, CAUSED BY A PESSARY WORN WITHOUT INTERRUPTION FOR TEN YEARS, AND FIRMLY ATTACHED TO THE CERVIX BY A BRIDGE OF TISSUE.

Dr. Wendt also presented the uterus and its appendages in this case, with the pessary still *in situ*. The history had been furnished by Dr. Haig, house physician of the St. Francis Hospital.

M. D——, aged thirty-nine years, native of Ireland, widow. Admitted to the St. Francis Hospital October 28, 1881; service of Dr. Lellman. She had suffered from rather obscure uterine symptoms for many years. About ten years ago a pessary had been introduced, and had not been removed since. Last May she began to suffer from occasional attacks of fever, with loss of flesh, failing appetite, and slight cough. Her symptoms grew progressively worse. On admission to the hospital there was great prostration, but no fever. There were some rather ill-defined pulmonary symptoms, and a tendency to diarrhœa, with very offensive stools. There was but little discharge from the genital tract. A vaginal examination revealed the presence of a pessary, which was firmly lodged high up in the vagina. Attempts to remove the same proved unavailing, as it seemed to be firmly attached to the uterus. The patient grew steadily worse, and died, apparently exhausted, on the 4th of November, at 1 P.M.

At the autopsy, which was made on the following morning, moderately extensive lesions of a catarrhal phthisis were found. The apex of the left lung was tranformed into a cheesy mass, but breaking down was nowhere seen. About the uterus, and especially posteriorly, the evidence of repeated attacks of perimetritis were visible. In the vagina a pessary was securely lodged. The instrument had a roughened surface, and showed incrustations at several points. The vagina below the pessary was much contracted. A bridge of completely organized tissue helped to secure the instrument firmly fixed in its position. This bridge was about half an inch wide and several lines in thickness. It extended from the posterior surface of the cervix over the pessary to the wall of the vagina, and was situated exactly in the median line.

The bladder was contracted, and contained about two ounces of a thick, purulent fluid. The uterus showed no flexion, but looked small and atrophic. Tubal dropsy existed on one side. The ovaries appeared normal.

In this case, probably, no doubt could exist that whatever condition had originally prompted the introduction of the pessary, its presence in the vagina for so many years had had a highly deleterious effect upon the patient, both locally and constitutionally. It had unquestionably favored perimetritic processes, and was probably the sole cause of the existing purulent vesical catarrh. The discharges incident to its prolonged presence had been a constant drain upon a constitution already weakened by pulmonary mischief. The practical lesson to be

derived from the study of this case was, therefore, readily seen. It was to the effect that too much care could not be taken in impressing upon the minds of the patients the necessity of occasionally removing pessaries, even if the use of such instruments was to be persisted in for a long period. Probably in this case the patient's life had been materially shortened by negligence in this respect.

TUMOR OF THE CEREBELLUM (ALVEOLAR GLIO-SARCOMA).

Dr. Wendt also presented a brain with the following history, furnished by the house physician, Dr. Haig: James D. S——, forty-two years of age, a native of the United States, married, and a carpenter, was admitted to the service of Dr. Lellman, at the St. Francis Hospital, July 14, 1881. The patient's family history was unimportant. He had never had rheumatism or malaria. He had a chancre twelve years ago, but had no eruption, loss of hair, or sore throat. He had led a pretty fast life when a young man; has been a rather hard drinker. In 1864, while engaged on a war-transport, he was struck on the top of the head by a large piece of coal and remained unconscious for nearly four days, after which time he was able to gradually resume work without any feeling of distress in his head. The spot where he was struck is now marked by a deep cicatrix. About three years previous to admission he lost his hearing on the right side. This came on gradually, and some weeks elapsed before it became complete.

The patient was well otherwise up to two months ago, when he had vertigo with nausea, but did not suffer enough to confine him to his bed at once. Somewhat later he felt so weak that he was obliged to remain in bed. He had then no marked vomiting or headache. During the past six weeks he has eaten but little food, and has lost much flesh and strength. He had no pain or tenderness over abdomen. On admission to hospital, patient was quite anæmic, and very much emaciated. No disease of heart, lungs, etc., was discoverable. He complained of nausea, but there was no vomiting. He was so weak that he was unable to walk. The abdomen was slightly retracted. Respiration, 26; pulse, 100, weak, but regular. Urine: specific gravity, 30; alkaline. Repeated examination of it failed to show any abnormal constituents. Patient's treatment consisted of tonics and a liberal diet, and he seemed to improve for three weeks, when he was able to go about the wards and assist in light work. About this time he began to complain concerning his left ear. He was soon unable to hear, unless spoken to loudly. The ear was examined, and considerable inspissated cerumen removed. It was syringed daily with tepid water, but hearing did not improve, and in about three weeks on left side was entirely lost. He was then put on the iodide of potassium.

August 3d.—Patient complains very much of pain in head, principally along frontal region, with some at posterior portion just above nape of neck. It was so severe that it prevented him from sleeping. When walking he would stagger from side to side, but appeared to incline more to the right side than to the left. He was quite unable to stand still when he had his eyes closed. His abdomen was slightly retracted. Pulse, 110, weak, but regular. Has full control over bladder and rectum, also over muscles while in bed. He was then able to move his limbs in all directions. The appetite was very poor. Pupils somewhat dilated, but reacted well.

August 10th.—Patient remains in about same condition, except that abdomen is more retracted, and pulse slightly increased. Pain has to be controlled by opium.

August 17th.—Abdomen more retracted, "boat-shaped." Pulse, 120. Respiration varies from 8 to 14. Some respirations are short and shallow, while others are deeper. At different intervals he will stop breathing for nearly half a minute. Patient complains very much of his head, also of pain in stomach.

August 24th.—Patient somewhat better as regards pain in head, but pulse remains at 120 to 130. Respiration, 13; abdomen still markedly retracted. Has power to move all his vessels while in bed, but he is so weak that he is unable to walk. Urine and fæces passed normally.

September 3d.—Pain in head entirely gone. Patient sleeps well and appetite good. Abdomen still retracted. Pulse, 130, weak, but regular.

Patient continued as above until about October 1st, when pain in head returned with increased severity. The pulse still remains 130. Respiration, 7 to 14. Pain in head so severe that it has to be controlled by opiates. Has had no paralysis of any of his muscles, but cannot walk, as he is too weak. Patient is very much emaciated, and unable to digest much food. Pupils still equally dilated on both sides. Is constantly handling penis, so that this organ is very much inflamed. Has also developed several bedsores on sacrum and thighs.

October 10th.—Patient began to develop pulmonary œdema. Pulse, 140. Respiration, 10 to 13. Abdomen very much more retracted than formerly. Incontinence of urine and fæces. Œdema and congestion of lungs increased until October 15th, when the patient died.

In view of the peculiar symptoms, *i.e.*, the auditory disturbances, the change in breathing, the staggering gait, considered in conjunction with other manifestations—a diagnosis of cerebellar tumor was made during the life of the patient. Dr. Lellman decided to give him the benefit of the doubt as to the specific nature of the growth, and it seemed at first as if the antisyphilitic treatment was attended with a decided amelioration of the morbid phenomena. Subsequent events, however, showed that the tumor was not a gumma, but an alveolar sarcoma, and that, consequently, the apparent improvement was accidental.

At the autopsy, no noteworthy changes in the organs of the trunk were discovered. There was profound anæmia, and the emaciation incident to long suffering. On removing the calvarium, the dura mater appeared normal, the longitudinal sinus contained a thick clot of blood, and the other sinuses appeared filled with dark fluid blood. The pia mater, especially of the convexity, and particularly in front, was somewhat thickened, opaque, and excessively vascular. Some abnormal adhesions also existed between it and the cerebral substance. In other respects the cerebrum appeared healthy.

The left lobe of the cerebellum was almost entirely replaced by a neoplasm which had a pale pinkish color, and was of rather firm consistence. Externally, however, the configuration of the parts was not much altered, as a covering of apparently healthy cerebellar substance hid the growth from view, except at the under surface and adjoining the medulla oblongata. Further examination revealed the fact that the growth was distinctly circumscribed, and surrounded by what appeared as a thin capsule. A gelatinous substance separated the tumor from the pons and medulla. Partial destruction of the

processus ad pontem and the processes ad medullam was evident. The portions of the cerebellum which remained intact, or were only mechanically altered by compression, were a layer above the horizontal fissure, and some of the superior portions of the square and semi-lunar lobes.

On cross-section, the fleshy hue of the growth was seen to be offset here and there by paler areas, and the whole surface was sprinkled over with dots and streaks of a red color. Breaking-down had taken place in a few places, thus giving the growth a spongy appearance in those localities.

Microscopically examined, the tumor was ascertained to belong to the glio-sarcomata. But its structure was not in all respects a typical one. The rounded corpuscles, about half as large again as leucocytes, which made up the main bulk of the sarcoma, were in many places arranged in groups of a distinctly alveolar appearance. Such aggregations of cells also very plainly showed a surrounding reticulum of not over-delicate connective tissue. Some parts of the tumor were constituted almost exclusively of these round cells, although even here a delicate fibrillar stroma could be discovered. There was an abundant supply of blood-vessels within the neoplasm, showing no uncommon feature, save, perhaps, the great delicacy of the vascular walls.

Finally, it may be stated that a careful naked eye and microscopical examination of the cerebral and cerebellar blood-vessels revealed no syphilitic alteration.

Dr. Robert Newman presented a specimen of

CARCINOMA OF THE BREAST.

[Vid. page 706.]

Dr. John A. Wyeth presented a specimen with the following history:

MYXO-SARCOMA OF NECK—LIGATION OF COMMON INTERNAL AND EXTERNAL CAROTID, SUPERIOR THYROID, LINGUAL AND FACIAL ARTERIES, AND THE EXTERNAL JUGULAR VEIN.

John O——, fifty-four years of age, Scotchman, long resident of New York; sexton. Eighteen months prior to March, 1881, noticed a swelling on left side of neck. Health had been good up to three years before this time, when he began to decline without any appreciable cause. Had been admitted to the New York Hospital in January, 1881. An operation for removal of the tumor was not recommended—injections of arsenic were here used. Patient came under his observation in April, 1881. At that time there was a prominent bulging of the left side of the neck from the lower jaw to the clavicle. The trachea was displaced, the pomum Adami being pushed one inch to the right of the median line. His breathing was extremely difficult, and he suffered intensely from pressure of the mass on the brachial plexus. The patient was anxious to be operated upon. Dr. Wyeth explained to him that the tumor was malignant in all probability, and would recur if removed, and that his chances of living through an operation were very small. The patient insisted on something being done, and with the advice of Dr. Willard Parker, who kindly saw the case in consultation, Dr. Wyeth consented to attempt the removal of the mass, or as much of it as pressed upon the trachea and brachial nerves.

Assisted by Drs. Parker, Stimson, Banks, Symington, Alexander, and Ayers, he performed the operation on April 28, 1881. The incision extended from the ear to the clavicle. The external jugular was tied and then the sterno-mastoid and omo-hyoid muscles were divided. Dissection into the tumor revealed that the carotids and their branches, the internal jugular vein, and the pneumogastric nerve were imbedded in its meshes. He tied the common carotid with a cat-gut ligature about the size of an A violin string. The external and internal carotids, the facial, lingual, thyroid, and occipital arteries were also tied with two ligatures and divided between them. The pneumogastric nerve was dissected out for about two inches. At this step of the operation it was discovered that the tumor involved the subclavian artery and vein and the thoracic duct, and that its complete removal was impossible. Portions of the upper and outer sphere were removed in order to relieve as much of the pressure as was possible, and the wound was closed, with drainage secured. About twenty-five ligatures were applied. The hemorrhage had not been extensive. The patient became conscious three or four hours after the operation, and complained of intense pain in the arm and wound. Morphine was administered hypodermically. He remained quiet after this; became unconscious later; gradually sank, and died, twenty-six hours after the operation, from exhaustion due to the long-continued suffering and bad condition, but chiefly to the operation.

The microscopical examination, made by Drs. Welch, Wardwell, and himself, showed the tumor to be myxo-sarcoma.

TUBERCULOUS DEGENERATION OF LYMPHATIC GLANDS OF THE NECK.

Dr. Wyeth also presented a patient with the following history, furnished by Dr. Anderson, of the house staff at Mount Sinai Hospital:

Henry F——, twenty-two years of age, butcher, resident of New Jersey, and a native of the United States. Father living and healthy; mother died of consumption; one brother living and healthy; two sisters living—one in good health, the other is said to have "trouble around her heart;" two brothers dead, aged five and fifteen years, cause of their death, unknown; one sister, aged thirty-two, died of consumption. Patient had been perfectly well up to three years ago, 1878. Then a small lump, the size of a pea, appeared on the left side of his neck, gradually growing larger. At various times since then other such lumps have appeared and increased in size. In the spring of 1881 he was admitted to the New York Hospital, where he remained one week. He says he was informed that no operation would be undertaken on him, and he was discharged. He then consulted Dr. Jacobi, who sent him into Dr. Wyeth's service, at the Mt. Sinai Hospital—admitted June 13, 1881. At this time there was a protrusion of the left side of the neck from the jaw to the clavicle, projecting as far out as the level of the inferior maxilla. He was suffering considerable pain. On June 19th Dr. W. removed some enlarged glands, about ten in number, and varying from a hazel-nut to a walnut in size. This operation was in the lower half of the neck. The external jugular vein was tied. Owing to the general hemorrhage, the operation was tedious, lasting two hours.

Patient recovered promptly, and on July 10th, the incision was continued to the tragus of the ear, and about twenty more tumors, one or two of large size, were removed. The sterno-mastoid muscle was divided, as well as the omo-hyoid. Five glands were removed from the sheath of the internal jugular vein, to which they were closely adherent. About thirty

ligatures were applied in both operations. No vessels of any magnitude were divided. The patient recovered well. November 23d he was still well, and the wound had healed. No trouble from the division of the mastoid muscle. Drs. Welch, Wardwell, and himself had examined the tumors, and found them tubercular, the central portion being degenerated and occupied by masses of tubercle, and the corpuscles thickened, with increase of the spindle-cells of connective tissue.

(To be continued.)

## Correspondence.

### THE BLOOD FROM THE SPLENIC ARTERY.

To the Editor of the Medical Record.

Sir: I read the answer to my letter, from Dr. Hammond, with a great deal of interest; but the main issue is avoided altogether. Will Dr. Hammond reiterate that he believes a pint or more of clotted and fluid blood could have been *pushed out* of the arteries, in President Garfield's case, by the embalmer's injection? That is the question. That a certain small amount of blood, under certain conditions, normal or abnormal, may be in the arteries after death, is well known. But practically the arteries are empty after death.

New York arteries may be peculiar; but here, Prof. H. C. Chapman, when he was coroner's physician, examined hundreds of bodies, and always found the arteries empty.

Dr. Morris Longstreth, of the Pennsylvania Hospital, only last week, without any reference to this discussion, examined the splenic arteries of two bodies, and found them absolutely empty. The injection thrown into the arteries in the President's case was a "good thing," because it proved the leak which existed before death. The solution of chloride of zinc escaped through the leak, as it escapes through a rent in a hose when the fireman is testing the hose. He screws up one end tightly, and drives water through the other end under pressure. If there is a hole, the water spurts out: and so it was with that famous splenic artery. Very truly your friend,

Wm. Hunt.

Philadelphia, December 12, 1881.

### FLORIDA IN WINTER.

To the Editor of The Medical Record.

Sir: On my way from Sandford to Jacksonville and home, it occurred to me that a brief letter to the Medical Record might have a little value for those of your readers who may not have seen Florida, and yet are called to give advice to invalids in search of recreation in winter. The choice of route from New York to Florida must be determined by the preference for sea or land transportation. For those who prefer the former, the steamers from New York to Savannah are said to be commodious, seaworthy and in every other condition admirable. It is difficult to imagine any railway travelling more satisfactory than that over the Pennsylvania Railroad, and by the Coast Line through Weldon, Charleston, and Savannah, and the "Short way" to Jacksonville. You may take a "Pullman Sleeper" at 9 P.M. at Jersey City, and go in the same car continuously to Jacksonville. Although the way-side "eating places" are not positively bad, I would advise travellers to take a lunch-basket, stocked with such articles of food as their experience has shown to be nutritive and digestible, so that they may have the periods of time allotted for eating at stations for exercise. A cup of coffee of fair quality may always be got at such stations to add to the provisions carried. Although there are advantages connected with the use of the "through Pullman," I agree with our sanitary authority, Dr. Rauch, of Chicago, that "one night out" is as long as a Pullman Sleeper should be used without change. In twenty-four hours a Pullman car becomes unclean, and it is not possible for the porter to cleanse it efficiently while the passengers are in it. As a sanitary precaution, transfers should be made at least once in twenty-four hours, and the Pullman then vacated and dismantled, carpets removed and shaken, mattresses aired, and the interior of the car thoroughly scrubbed out. I do not know how often the mattresses of the Pullman cars are made over, but my conviction is that they are usually unclean. They are covered with stuff, and so upholstered as to be kept too long in use, and therefore get saturated with animal exhalations. It would be better to have them made over, and the hair disinfected, much more frequently than they are. They should also be covered with washable slip-covers, to be removed and cleansed after every twenty-four hours of use. The colored blankets, although good in quality, have a suspicious odor oftentimes, as though they had been shut up with the mattresses after having been saturated with animal exhalations. It is not congenial to suggest the existence of these faults, but I do it in the interest of health, and to be helpful to a company which has done so much to mitigate, if not remove entirely, the horrors of night-travel. The water-closets of the Pullmans are not yet perfect. The fault is, however, largely with the porter. That servant is not always well trained, or furnished with the appliances with which to cleanse the closets. It would be well to provide, in the construction of the Pullman car, a small, well-lighted and ventilated closet in which to keep the cloths and brooms needed for the thorough cleansing of the car, and to give better ventilation and lighting to the closets in which the porter stores the clean and soiled linen and towels.

I observed that the conductor on our sleeper made his toilet in the open car in the presence of the ladies, and that we thus had an unsolicited opportunity of observing his suspenders and the magnitude of his sleeve buttons. This little offence should be prevented, and the porter and conductor kept up in tone by very frequent inspection, discipline, and reward.

At Jacksonville, the experience in Florida proper commonly begins. There are several excellent hotels in the town, and many inducements for a more or less prolonged sojourn. The taste of the American people is unmistakably in favor of large hotels, and the so-called conveniences which they afford. The proprietors of such caravansaries make most commendable efforts to supply the wants of their patrons.

Of course medical men know very well that the "population-rate" of a large hotel is so great as to be incompatible with the highest salubrity, even when every possible sanitary precaution is used. They are not to be blamed if the vast majority of their patrons know nothing about sanitary matters, and care less. They meet fully the demands of the average intelligence of their guests. A sanitarian has a very high ideal, and, therefore, finds

in the population itself of a hotel, a condition making a high degree of salubrity impossible. Few people like ventilation, and the majority of the occupants of a hotel demand the exclusion of fresh air from halls, corridors, dining- and sitting-rooms, and prefer to live in an atmosphere which would poison a toad. At all sanitaria, hotels should be built upon the cottage plan, and those enormous dining-rooms, in which hundreds of human beings congregate to feed, and, meanwhile, pollute each other with crowd-poison, abolished. In large cities such huge hotels are, perhaps, necessary evils, but the day will come when, even there, more open fireplaces and new methods of forced ventilation, and the providing of baths and water-closets for common use in detached portions of the building, will lessen the evils of the present congregate plan. In this State a somewhat new problem presents itself, in the fact that all houses should be constructed without cellars, and so raised on underpinning as to allow a clean sweep of light and air beneath them. Indeed, it is a question whether such a mode of construction should not be adopted everywhere for dwellings. I have for more than twenty years believed that cellar-atmosphere is a most prolific cause of disease and death. I believe that it increases seventy-five per centum the risk from malarial disease all over our country. Through this State the native population, as by an instinct, raise their simple cabins three or four feet above the ground, and allow air and light to pervade the space so made beneath the ground floor. I advise all travellers to avoid those hotels and other domiciles in the South which are not so constructed.

The avenue into Florida is the St. John's River. Upon it are excellent steamboats, officered by an admirable class of men.

Nowhere, in my very extended travels, have I found men who understand their peculiar calling better, or discharge their duties with more intelligence and fidelity. They are sober, vigilant, and polite, and constantly striving to make the service, in which they take a just pride, better. They are fully aware of the defects in the service, and are diligently striving to remove them, and to add to the comfort of the travellers whom they so willingly endeavor to please. The sail on the St. John's to Sandford is full of interest. The river is like a chain of lakes. Lake George, the largest of these expansions, is seventeen miles across. The river varies in depth from four to twenty-five feet. It is tidal for about a hundred miles from the sea, and has a current outward of about one and a half to two miles an hour. The shores are nowhere high, but vary in altitude from the water-level to fifteen or twenty feet, and are clothed with a growth of cypress, oak, and pine, and, if you go southward, palm trees. You pass many orange groves, and at every landing see preparations for packing and shipping the products of these groves, and the other fruits of the soil.

Everywhere there is movement. There is a universal spirit of enterprise and industrial activity, and the average Floridean is full of enthusiasm about his native or adopted State. The country is being rapidly settled, and the planting of orange groves, and other vegetables and fruits, is going on with energy, and an ardor that is amusing and instructive. The value of the crop is immense, and the returns unquestionably satisfactory. What misfortunes may overtake the planter in the future we cannot prophesy. It is fair to suppose that he will not be free from the common vicissitudes of the agriculturist. Of the general salubrity of the country, I have no doubt. Of its value as a health resort, I have also no doubt. It is not only advantageous for the catarrhal, rheumatic, and pulmonic invalid, but for the jaded and head-worn, or so called over-worked, man of business. I believe that nowhere in our land can a jaded man or woman so quickly get relief in the winter as in Florida. There is a quality in the winter atmosphere which is most soothing and rest-giving. The winter transportation is conducive to such ease and comfort as the jaded nervous system requires, and the inducements to out-of-door life are numerous and irresistible. The winter season is the *dry season*, and there are more entire days between November and April suited to out-of-door life than anywhere on this continent, unless it may be in some unfrequented portions of Mexico. The drives through the woods are easy and attractive; the fishing and gunning are good; and for those who enjoy the field of nature, there is everything in the flora to captivate and satisfy. With ordinary care, I believe that there is not so much danger of contracting disease from local sources, from December 1st to April 1st, on the St. John's River and the frequented parts of Florida, as there is in the health-resorts of France and Italy. Of course there are not in Florida the æsthetic and social provisions of the latter countries, or those products of old civilization which afford, from historic sources, amusement and instruction; but for the lover of out-of-door life, the student of nature, and observer of climatic advantages, there is much to be desired.

C. R. Agnew, M.D.

St. John's River, Fla., December 9, 1881.

---

Case of Epilepsy Cured by Enucleation of the Eye.—Dr. H. Rosencrans, of Elgin, Illinois, relates, in the *Chicago Medical Journal and Examiner*, the following history: "The patient here referred to was cured of epilepsy by the enucleation of an eye. Mr. K——, of Indianola, Texas, for years past had been troubled with epileptic fits. The history given by himself to me was that about ten years ago he lost the sight of one of his eyes by taking "cold" in it. Since then he has had spells of his eye inflaming, paining him very much, and usually bringing on an epileptic fit. I advised its enucleation. I told him that it was possible, and even probable, that it might be the means of curing him of his epilepsy. He consented to its removal. On the 9th day of February last I removed it. While under the influence of chloroform, and while I was in the act of removing the eye, he was seized with a fit of epilepsy, and it took four strong men to hold him on the operating table. I kept up the chloroform, and, as soon as his fit left him, lasting about ten minutes, I at once removed the eye. With cooling and antiseptic dressing the socket soon healed. I then, as a constitutional remedy, put him on the use of bromide of potassium. He has had no epileptic fit since."

Zulu Clysters.—The Zulus have an apparently very pleasant and efficacious way of administering an enema. The individual in need of an injection is grasped by two vigorous natives and made to stand on his head. While in this position a funnel, made by sawing off the tip of a cow's horn, is introduced into the rectum. Water *ad libitum* is then poured into the instrument, which done, the parties disperse, satisfied that nature, thus assisted, will accomplish the desired end.

# New Instruments.

## A NEW DILATOR.

By SENECA D. POWELL, M.D.,

ASSISTANT TO THE PROFESSOR OF CLINICAL SURGERY OF THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF NEW YORK.

THE accompanying cut represents the dilator closed and open. The instrument consists of four parallel, rounded, smooth steel rods, supported and united each by two tempered steel brackets, all nickel-plated. It is nine and one-half inches in length, and the dilating part is four inches. It is opened by turning the screw *a*, and the indicator on the dial plate gives the exact circumference in millimetres of the dilating portions. The instrument, when closed, numbers twenty millimetres, and when opened to its fullest extent is fifty millimetres. It was originally devised by me to treat strictures of large calibre situated in the penile portion of the urethra, so as to avoid slitting the meatus, as I frequently found patients who objected to this, so often necessary, procedure. If the meatus will admit a No. 20 sound, the stricture can be dilated to any extent by this instrument. It avoids the introduction of more than one instrument at a sitting. The dilatation, which is parallel, can be made so gradual, and the pressure is so equally distributed, that neither pain, irritation, nor laceration need result. I have used this instrument a great many times during the last five months, and Professor James L. Little has used it in a number of cases, and in each instance with satisfactory results. There is no danger of catching the mucous membrane when closing the instrument, as each bar and joint is rounded. I have had a rubber cover made, which, being slipped over the closed instrument, gives additional security against any pinching of the membrane. I have used this dilator for dilating the female urethra with complete success, and know of no instrument which possesses equal advantages for this purpose. It can likewise be used for dilating the cervical canal, and should any surgeon so wish, can be manufactured with gently curved parallel blades. I am having an instrument constructed upon the same principle for treating strictures of the rectum. In introducing it to the notice of the profession, I claim that it is the only dilator as yet devised by which a stricture can be dilated to the normal calibre of the urethra without interfering with a moderate-sized meatus. It is the only perfect parallel dilator containing four blades which has yet been brought before the profession. This dilator was made for me by Geo. Tiemann & Co., of this city.

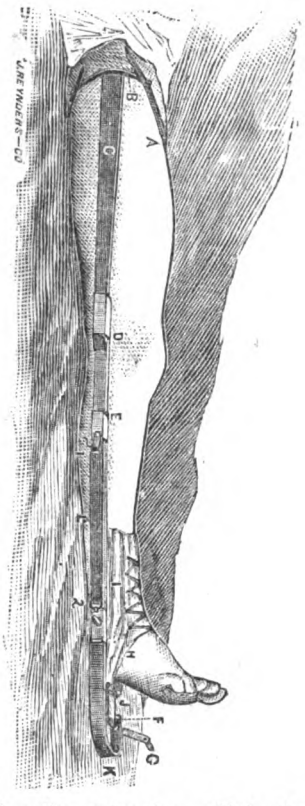
42 WEST FORTIETH STREET, NEW YORK.

## AN APPARATUS FOR EXTENSION AND COUNTER-EXTENSION.

By WILLIAM BUNCE, M.D.,

OBERLIN, OHIO.

I WISH to call the attention of the profession to the following description of an instrument that meets perfectly all that is required in extension and counter-extension in the treatment of fractures, dislocations, and diseased joints. It is simple, durable, and easily applied, and can be adjusted to the limb in any position, flexed or straight. Its power of extension is unlimited, and can be applied all at once, a little at a time, or at any time during treatment, without in any way disturbing the dressings or instrument; or, if desired, a constant elastic extension to any extent can be kept up during the entire treatment. It can be applied to the arm as well as to the leg; to an adult or child. It can be made useful in dislocations as well as fractures, and allows free manipulation during extension.



The following will explain the instrument and its application: A is the perineal pad, buttoned on to B, the perineal pad-adjuster, which is fastened to the upper end of the counter-extending bar C. D and E are sliding-bars, by which any desired length can be obtained, and to which the rubber adjustant for elastic extension is attached at the points Nos. 1 and 2. F is a round bar, to which a crank, G, is attached, the turning of which winds up the cords, J, securing the extension. K is the head of the instrument curving around the foot. H are the laces for adjusting the garters, I.

In applying the instrument, it will be readily seen that by turning the crank any amount of extension can be secured, which is firmly held by the thumb-screws, and if desirable the crank can be removed. When an elastic extension is desired, it can be obtained to any amount by adjusting the rubber belt to the points designated on the sliding-bars and putting it to the stretch and turning the thumb-screws so as to hold it, then adjusting the instrument to the limb, and by turning back the thumb-screws, let the full force of the rubber apply directly to the limb.

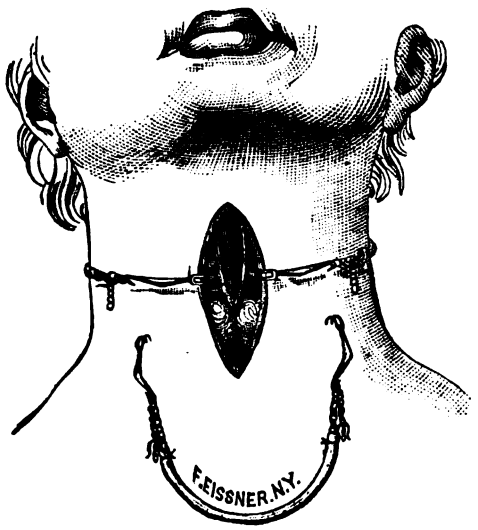
Any kind of appliance, felt or splint, or dressing, can be applied or used at any time without disturbing the instrument. Adhesive straps can be substituted for the perineal pad and garters.

## AUTOMATIC TRACHEAL RETRACTOR.

By A. CAILLÉ, M.D.,

NEW YORK.

The accompanying cut represents a small instrument, which I have found useful when performing tracheotomy. It consists of a rubber-band, at each end of which is fastened a short brass-chain, and attached to the latter are two curved and sharp hooks. The chains are so adjusted that they can be lengthened out or shortened at will, thereby adapting the retractor to small or large necks. In performing tracheotomy, the surgeon is usually fortunate if one trustworthy assistant be on hand, who is expected to administer the anæsthetic, and assist at the wound as well. Now, if the patient is in any way troublesome (as is frequently the case), the operator may



not be able to proceed with the necessary ease and facility. In such a case the automatic retractor will be of service; it will keep the edges of the wound well apart; it may be hooked into the fascia as the several layers are divided, and finally into the tracheal wound. The trachea may be examined at leisure, and there need be no haste in getting the tube into its place. The instrument may be used as a general refractor in operations requiring careful dissections, in different parts of the body; but it is especially applicable to the neck.

303 BROOME STREET.

## ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from December* 11, 1881, *to December* 17, 1881.

McCLELLAN, ELY, Major and Surgeon. Relieved from duty at Fort McHenry, Md., to proceed to Fort Trumbull, Conn., and relieve Asst. Surgeon W. H. King. S. O. 224, Department of the East, December 15, 1881.

KING, W. H., Capt. and Asst. Surgeon. When relieved by Surgeon McClellan to repair to Fort McHenry, Md., and report for duty at that post. S. O. 224, C. S., Department of the East.

HOFF, J. V. R., Capt. and Asst. Surgeon. Granted leave of absence for one month. S. O. 222, Department of the East, December 12, 1881.

PERLEY, H. O., Capt. and Asst. Surgeon. Having reported in person at these headquarters, will report to the Commanding Officer, Fort Columbus, N. Y. H., for duty as assistant to the post surgeon and attending surgeon at these headquarters. S. O. 224, C. S., Department of the East.

GORGAS, W. C., 1st Lieut. and Asst. Surgeon. Granted leave of absence for one month, with permission to apply for an extension of one month. S. O. 150, Department of Texas, December 3, 1881.

RAYMOND, HENRY I., 1st Lieut. and Asst. Surgeon. Relieved temporarily from duty at Alcatraz Island, Cal., and to report to the Commanding Officer of the Presidio of San Francisco for duty at that post. S. O. 214, Military Division of the Pacific and Department of California, December 9, 1881.

MADDOX, THOMAS J. C., 1st Lieut. and Asst. Surgeon. Having completed the duties assigned him under S. O. 248, November 3, 1881, from A. G. O., will report in person to the Surgeon-General, United States Army. S. O. 238, A. G. O., December 15, 1881.

LOCALIZATION BY THE EYES.—Professor Helmholtz recently addressed the Physical Society on the localization of objects by the eyes. We estimate distance with one eye by the outlines of the more distant objects being covered by the nearer one where they meet, and by the shadows thrown by the anterior objects. These conditions are very rarely overpowered by others, as for instance, binocular vision. This is shown by Dove's pseudoscope, and the fact that closing or blinding one eye makes little difference to the power of judging distance, especially when not very close to the eye. The relative shifting of objects as the eye is moved from side to side, or to and fro, or up or down, which may be called the parallax of motion, is also a strong factor in estimating distance. He concludes from a study of the stereoscope that the perception of the absolute convergence of our eyes is very indistinct, and that only differences of convergence related to apparently near or distant objects produce the stereoscopic effect.

THE SANITARY ENGINEER.—Our excellent and enterprising contemporary, *The Sanitary Engineer*, has been changed to a weekly journal. It is always welcome to our table, and is always filled with interesting and instructive material bearing on its specialty.

THE DIFFICULTY IN FINDING A BALL AFTER IT HAS PENETRATED A CAVITY IN THE HUMAN BODY.—Dr. Benjamin R. Swan, of San Francisco, Cal., writes: "I have just taken my RECORD of October 22d from the post-office, and am delighted to see that some one has spoken upon 'the difficulty in finding a ball in the dead body.' I was on the point of doing so myself, as it seemed to me that the public were, through the press, being wrongly instructed by both lay and *medical* instructors. No one could speak more to the point than Dr. Beach, and I wish simply to say that my experience endorses his words in every particular. You are aware that I filled the office of coroner in this city and county three years. My annual reports, which you have, 1874–77, give one hundred and twenty-five deaths from gunshot wounds. I can therefore claim some experience, as in nearly every case an autopsy was made. The history of some of these cases is almost incredible. I think in two cases we gave up the search; could not find the ball. In a third case, like the two mentioned, there was a wound of entrance in the abdomen, none of exit. It was a criminal case, and a question of *two* pistols of different calibre made it of prime importance to find the bullet; over *six* hours were spent; the ball had entered the cavity of the abdomen, wounding, *I think*, the intestines, and there trace was lost. The body was eviscerated, etc., and we finally determined that the ball *must* have passed out *somewhere*, though we could find no wound; but after, as I remarked, six hours' work we found the ball lodged in the muscles between the right shoulder-blade and the ribs adjacent, the track of the ball obliterated. During the late terrible ordeal *I*, like every other doctor, was asked, 'Where do you think that ball is?' My invariable reply was, 'Judging from my experience when a bullet enters a human body and penetrates a cavity, and particularly that of the abdomen, its location is a simple unknown quantity.' This opinion is greatly strengthened, if possible, by the President's case, and I feel quite sure that in a given case of gunshot wound, if the ball cannot be *readily* found, it had better be left alone. And I think, too, that the medical gentlemen who have been so fierce to have the ball '*gone for*' as the one thing needful, if they will put themselves under the tuition of Dr. Beach, will change their opinions.

PAPAIVA.—Papaine, also known as the vegetable pepsin, is extracted from the *carica papaya*. The important subject of vegetable digestive ferments has made a great step forward, and the satisfactory results obtained by Bouchut and Wurtz in their observations, serve to direct the attention of the profession to the great clinical and therapeutical value of papaine. The milky juice which contains the papaine is white, whether coagulated or not, slightly bitter and styptic, quite devoid of acrid taste, and slightly acid in reaction. It is so rich in albumen and fibrin that Vauquelin likened it to the blood deprived of its coloring matter. It is obtained by incising the green fruit, and is immediately bottled and shipped, either pure or mixed with ten to twelve per cent. of alcohol, to prevent fermentation. The pure juice soon coagulates, that which has been mixed with alcohol remains fluid, and, if undisturbed, separates into a clear liquid, and a white precipitate, consisting in great part of albumen, fibrin, and considerable papaine is also thrown down. Another precipitation with alcohol yields crude papaine; which, after several washings with alcohol, is dissolved in water, which takes up only the alkaloid. A final precipitation throws down the pure papaine. In proper doses the drug has an energetic digestive action upon all albuminoid matters, possessing the properties of highly active pepsin, over which substance it has the advantage that its effects are always constant and identical. In an acidulated solution its action is still more energetic. It does not bring about mere solution of the albuminous substances, but causes a true digestion, producing peptones of milk, fibrin, meat, and eggs, which are completely dialyzed, and consequently readily assimilable. Very successful experiments were made by Dr. Bouchut at the Congress of Rheims. The results of artificial digestion confirm the facts observed in the clinics. In gastralgia, dyspepsia, lientery; in all cases of gastric derangement from insufficient secretion of gastric juice, papaine, in the form of a syrup, an elixir, etc., rapidly re-establishes the normal digestion. It is used with great success in gastritis, gastralgia, gastro-enteritis, diarrhœa, vomiting of children, etc.—*Riv. Clin. di Bologna*, August, 1881.

AN EXAMPLE WORTHY OF IMITATION.—In the city of Brussels, whenever a birth is registered the Registrar hands to the parent, gratuitously, a little pamphlet of five pages containing short and plain directions for the management of children. In Paris the mortality among infants is so enormous that it is proposed to introduce a similar practice there.

MENTAL ADAPTABILITY IN SCIENTIFIC WORK.—"But that which I would chiefly note, in relation to the great variety of minds which are here, is that it is characteristic of that mental pliancy and readiness for variation which is essential to all scientific progress, and which a great international congress may illustrate and promote. In all the subjects for discussion we look for the attainment of some novelty and change in knowledge or belief; and after every such change there must ensue a change in some of the conditions of thinking and of working. Now, for all these changes, minds need to be pliant and quick to adjust themselves. For all progressive science there must be minds that are young, whatever may be their age.

"Just as the discovery of auscultation brought to us the necessity for a refined cultivation of the sense of hearing, which was before of only the same use in medicine as in the common business of life; or, as the employment of the numerical method in estimating the value of facts required that minds should be able to record and think in ways previously unused; or, as the acceptance of the doctrine of evolution has changed the course of thinking in whole departments of science, so is it, in less measure, in every less advance of knowledge. All such advances change the circumstances of the mental life, and minds that cannot or will not adjust themselves become less useful, or must at least modify their manner of utility. They may continue to be the best defenders of what is true; they may strengthen and expand the truth, and may apply it in practice with all the advantages of experience; they must secure the possessions of science and use them well, but they will not increase them.

"It is with minds as with living bodies. One of their chief powers is in their self-adjustment to the varying conditions in which they have to live. Generally those species are the strongest and most abiding that can thrive in the widest range of climate and of food, and of all the races of men they are the

mightiest and most noble who are, or by self-adjustment can become, most fit for all the new conditions of existence in which, by various changes, they may be placed. These are they who prosper in great changes of their social state; who, in successive generations, grow stronger by the production of a population so various that some are fitted to each of all the conditions of material and mode of life which they can discover or invent. These are most prosperous in the highest civilization—these whom nature adapts to the products of their own arts."—Sir James Paget, in *Popular Science Monthly* for October.

VENTILATION OF SEWERS.—The following inquiry from Mr. John Walter, M.P., proprietor of the *London Times*, touches on a subject that at this time is considerably agitated in England. We have requested one of our English contributors to send us full particulars of the condition and character of the sewers Mr. Walter refers to. When those are received, we may be able to add something to the reply here made, which is necessarily a general one.

Mr. Walter writes as follows, from St. Paul, Minn.:

"ST. PAUL.

"DEAR SIR: A question to which I desire to call your attention refers to the system now in vogue of ventilating sewers by means of open gratings in the streets and public thoroughfares, a system which I have heard defended as the only effectual means of preventing sewer-gas from finding its way back to the houses. I have, however, noticed in some places, and particularly on the road out of Shanklin in the Isle of Wight, on the way to Sandown, an intolerable stench arising from a sewer so ventilated, and I have heard complaints of a similar nuisance from visitors to Sandown itself. In London itself I have observed that these gratings, in certain states of the atmosphere, give out most offensive smells, which cannot be otherwise than injurious to health. What I should like to know is, whether by a proper system of flushing, such a nuisance can be prevented; and, if so, whether it should not be made compulsory on the sanitary authorities to see that this method is adopted for preventing it?

"Yours faithfully, J. WALTER."

The system of ventilating sewers by perforated covers at frequent intervals, is now widely practised both in Europe and this country, and is generally received by engineers as the best method yet devised. Occasionally trouble may arise, as in the case referred to by Mr. Walter, at Sandown. But we venture to say that the cause may be removed there, as it has been in many other places, by proper care. Without a more intimate knowledge of the circumstances and condition of the Sandown sewers than we now possess, we cannot define the cause except in a general way. We can say this, however, that it must be due to one or both of these two causes, viz.: an inadequate number of vent-holes, or an unnecessarily foul state of the interior of the sewer. If such foulness exists, it may arise from either one or a combination of several causes, such as the following:

*First.*—Improper planning, such as a deficient inclination, or excessive size, or improper form of section, rough materials, irregular gradients, badly devised junctions or branch inlets, angles favoring deposit, etc.

*Second.*—Poor workmanship, such as rough bricklaying and bad alignment.

*Third.*—Poor materials, either coarse and rough in texture, or perishing and crumbling from premature decay.

*Fourth.*—Want of proper care on the part of those having charge of the administration, such as want of flushing and cleansing, which are needed more frequently in some sewers than in others.

*Fifth.*—Inadequate protection at inlets to guard against the introduction of garbage or offal in solid form, or solid matter, which would favor the accumulation of filth, such as sticks, stones, gravel, silt, etc.

In short, if sewers are properly planned, well-constructed, and carefully looked after, the perforation of manhole covers for purposes of ventilation is not likely to lead to trouble, and such trouble, when it occurs, is generally a symptom of something wrong in one or more of the above particulars.—*Sanitary Engineer* of New York.

GULF-WEED IN EPILEPSY AND OBESITY.—Gulf-weed, in doses of gr. ij. of powdered extract every two hours, has been successfully used by Dr. M. Milton in a case of epilepsy, combined with, and as he thought, dependent on obesity.

The gulf-weed is especially useful in the treatment of obesity. Combined with a milk diet and diminution in salted and solid food, it acts very rapidly in reducing flesh without weakening the patient. Gulf-weed is entirely distinct from fucus vesiculosus.—*Maryland Medical Journal.*

LARGE DOSES OF MORPHINE IN PUERPERAL ECLAMPSIA AFTER CONFINEMENT.—Dr. James S. Cooley, of Luzerne, Warren Co., N. Y., sends us a report of the following case:

"Mrs. G——, primipara, aged about twenty-two years, was delivered of male twins at 9 A.M. of October 11th. She was attended by a local practitioner, who told me that the labor was perfectly natural, and lasting about six hours. Some time after noon of the same day, the patient complained of headache, which was not severe enough to cause any apprehension. About 11 P.M., however, fourteen hours after her labor terminated, the patient was seized with convulsions, and her physician was sent for in haste. Deeming the case a serious one, a second physician was summoned from a neighboring town, who arrived about 3 A.M. of October 12th. What treatment was adopted I do not know, but the convulsions continued during most of the day, October 12th, and the case was considered hopeless by both physicians.

"When I reached the house, at 6 P.M. of October 12th, the patient had just passed through the eighteenth convulsion, and I found her lying upon her back, rolling her head from side to side, twisting her body, her face and fingers slightly cyanosed, and wholly unconscious. The pupils were widely dilated, and her pulse 144. As soon as possible I gave, hypodermically, one-third of a grain of morphia, and administered per orem ten grains of chloral and twenty grains of bromide of potash. At 7 P.M. her pulse had fallen to 130. At 8 P.M. the chloral and bromide were repeated. At 8.15 P.M. she had her nineteenth and last convulsion, lasting about three minutes. I immediately gave one-fourth of a grain of morphia hypodermically. At 9 P.M. her pulse had fallen to 102. During the night five grains of chloral and ten grains of bromide of potash were given every hour. At 11.15 P.M., there being some indications of a return of the convulsions, one-third of a grain of morphia was given in the same manner as before, and at 9.15 A.M. of October 13th, just be-

fore leaving to visit other patients, I gave her one-fourth of a grain more.

"At 3 P.M. of October 13th I returned, and found some improvement in my patient's condition. Her pulse had lowered to 92, and there were no symptoms of an overdose of morphia, excepting a very profuse perspiration, and respiration being but fourteen to the minute. Her attendants insisted that she had voided her urine involuntarily, and in considerable quantity; but, the bladder seeming full, I introduced the catheter and drew off nearly three pints of urine. An examination per vaginam revealed nothing abnormal.

"At 9 A.M., October 14th, my patient began to show signs of returning consciousness, and recognized her friends. Mental processes were very slow, however, and she was disposed to talk but little. October 15th the milk fever came on, and the breasts seemed quite painful. Toward afternoon the patient was very restless, and conceiving the idea that she must die, called her friends about her and gave them her farewell messages. As a result of these circumstances, she became exceedingly nervous; her pulse flew up to 140 again, and her husband's apprehensions were so much awakened that I was sent for in haste. I sent all from the room, enjoined perfect quiet, and in a few moments my patient fell asleep, slept for some time, and awoke perfectly conscious, with no recollection of anything that had taken place subsequent to her labor. Her lochia, which had stopped for forty-eight hours, returned, her breasts became less painful, and thenceforward her recovery was as rapid as could be desired.

"Were I to have a similar case again, I would not hesitate to use the morphia in large doses, for I believe that one-half a grain or a grain on my first arrival would have saved my patient her last convulsion. I would ask the readers of THE RECORD to report their experience in the use of morphia in such cases."

DEATH OF TWO MEDICAL STUDENTS.—The students of the College of Physicians and Surgeons, who recently lost two of their fellow-students by death, George M. Fuller and Charles L. Breen, have passed suitable resolutions expressing their high appreciation of the deceased.

A PRACTICAL METHOD FOR PREVENTING THE SPREAD OF INFECTIOUS DISEASES IN HOUSEHOLDS.—Dr. Malcolm McLean, of this city, sends us the following practical method of preventing the spread of infectious diseases:

"For ten years past I have been experimenting with a simple method of quarantining cases of small-pox, scarlatina, diphtheria, measles, etc., and, as I have been able to get positively valuable results, I take the liberty of presenting it, simple as it is, to the profession for their trial. My plan consists simply in *filtering the atmosphere* which surrounds the patient through a carbolized or otherwise disinfectant sheet of muslin, which is closely tacked over the door-frames of the room in which the patient lies. I close all unnecessary doorways by tacking the sheet *all about* the frame, bottom, top, and sides. The *one* door which is needed for ingress and egress I protect by tacking a similar sheet across the top, down the whole side of the hinge side of the doorway, and down the lock side as far as within five feet of the floor. This filtering-sheet is made long enough to hang closely to the frame, and fall in folds upon the floor, where it is not tacked. By keeping such a sheet sprinkled with a solution of carbolic acid—I generally use Squibb's two per cent. solution—or other reliable disinfectant fluid, all, or nearly all, of the air of the infected room is *filtered* through a tissue which seems to *destroy the infection in its passage.* Moreover, the filter acts by moral effect, for it happens that intruders into the sick-room are very rare; and thus a great danger and prolific source of the disease is practically removed. Indeed, the whole household are reminded that there is a something within to be avoided. Of course the nurse must use care not to allow anything to be removed from the room in a condition to carry the poison without.

"After a fair trial of many years, assisted also by several of my brother practitioners (among whom I may mention Drs. I. B. Read, F. A. Smith, and J. A. Walther), I am able to state that, in a list of about fifty cases carefully observed, I have succeeded, in all but *two*, in confining the infection or contagion to the patient first attacked. In the two instances of failure I had abundant evidence that the quarantine was grossly neglected.

"Dr. F. A. Smith had the kindness to report to me a most interesting test of this method which occurred in his own hands last winter. In an institution which the doctor was attending professionally a case of well-marked scarlatina broke out in the midst of scores of young children who slept in the ward. The case was removed to the nurse's room, and there quarantined by means of the filter, according to the method described above. The consequence was that not another case occurred in the institution. On other occasions, where the usual modes of isolation were alone adopted, the same institution had been swept with epidemic force. Dr. Smith expressed to me his belief, founded on experience, that, without the method mentioned in the case reported, he would have had scores of cases on his hands in a fortnight.

"The simplest way to sprinkle the sheet is to pour the disinfectant solution in a flat dish, and dip a hair-brush in it, and with this throw the liquid over the filter. There are three positive points gained by using this method: 1st. The air of the sick-room is not mixed with the air in the rest of the house. 2d. Visitors are much less likely to visit the sick-room. 3d. The air of the sick-room is kept more easily at an even temperature.

"In all of my cases I have found it unnecessary to close the ordinary door, the filtering-sheet taking its place."

THE DIAGNOSTIC IMPORTANCE OF ODORS.—In a recent lecture Dr. Julius Althaus, of London, says:

"I must say a few words on the *diagnostic importance* of certain smells in the sick-room, which was formerly much insisted upon; indeed, whole treatises have been written on the recognition of disease by sniffing. Dr. Heim, who was the popular physician of the day at Berlin, some fifty years ago, recognized measles, scarlet fever, and small-pox by their peculiar smell on first entering a house, and before having seen the patient. Mr. Bernard, of Upton Park, has recently recorded in the *Lancet* two cases of small-pox in which the patients themselves perceived a dreadful smell, apparently just at the moment of being exposed to contagion; and one of them, when suffering from the eruption, said that his perspiration had the same smell as that which made him sick before. When attending Skoda's clinique in Vienna, twenty-five years ago, I noticed that this celebrated teacher was in the habit of sniffing when

approaching the bedside of patients suffering from the last stages of pneumonia, phthisis, typhoid fever, etc., and he would give a bad prognosis when he perceived what he called the 'cadaverous smell.' Mr. Crompton, of Birmingham, has noticed a peculiar earthy smell from the body a week or a fortnight before death, which, he says, has never deceived him —an appropriate illustration of the saying, 'Earth to earth.' Dr. Begbie distinguished typhus and typhoid fevers by the sanguineous (others call it 'mousy') smell of the former. Prof. Parkes has noticed a peculiar odor in the skin of cholera patients. A pungent smell in the chamber of a lying-in woman shows that lacteal secretion is well established, while an ammoniacal smell has been said to indicate the approach of puerperal fever. Many women emit a peculiar odor while menstruating, which resembles a mixture of blood and chloroform, and this is believed to arise, not so much from the discharge, as from the more pungent character of the sweat secreted in the axillæ. [At a meeting of the Neurological Society in this city, some time ago, the fact was stated that during intercourse women, in some cases, emitted a peculiar odor from the breath.] Persons of costive habit have a fecal smell; and this is also often noticed in hypochondriacs and lunatics. In uræmia, whether owing to kidney disease or to severe retention of the urine, a urinous odor is emitted by the body, and the presence of pus in some part of the body has been recognized by a peculiar warm, milky smell of the patient.

"Apart from the odor of the sick-room and the body generally, the smell of the sputa, urine, fæces, sweat, ulcers, etc., was carefully noted by the older practitioners and utilized for prognosis and treatment. Unquestionably there was much that was fanciful in such ideas; but, occupied as we are at present with the study of more precise and definite symptoms, we have, perhaps, gone to the other extreme in neglecting such signs altogether. Everybody has his own special odor, and this varies according to the circumstances of life, the food taken, and the state of health in which he happens to be. That it should be altered in disease, and that special diseases should have special odors, is only what one would expect; yet the increase of cleanliness and ventilation has, no doubt, done away with a large variety of smells which formerly used to assail the nostrils of the physician."

Treatment of Syphilis by Hypodermic Injection.—Dr. Martineau has published the result of a large number of cases of syphilis treated by a new method. This consists in the hypodermic injection of the following mixture:

| | | | |
|---|---|---|---|
| ℞. | Powdered peptone..... | grammes | 9 |
| | Ammon. chlorid..... | " | 9 |
| | Hydrarg. bichlorid..... | " | 6 |
| These are dissolved in | | | |
| | Glycerin..... | " | 72 |
| | Aqua..... | " | 24 |

This solution is of such strength that an ordinary French hypodermic holds 10 milligrammes (gr. ⅙) of bichloride of mercury.

This solution is injected subcutaneously, the dose employed varying from gr. $\frac{1}{18}$ to gr. $\frac{1}{4}$ of the mercury. Three hundred and seventy-two patients were treated with three thousand eight hundred and thirty-eight injections, and no abscess or slough ever resulted. No stomatitis or salivation is caused by this method, although very large doses are at times used. The rapidity of its effects is said to be marvellous.

Porro's Operation in England.—Mr. Spencer Wells recently performed a combination of Freund's and Porro's operations for the first time in England. The patient was a woman, aged thirty-seven, between five and six months in pregnancy, and suffering from epithelioma of the cervix. Very little blood was lost, and the woman was doing well six days later.

The State Charities Aid Association on Bellevue Hospital.—In the recent annual report of this association, the Committee on Hospitals says that it had discussed many questions relating to hospital building and management, having also distributed its publications throughout this and other States. In regard to building open-air pavilions for the sick, the committee condemned the practice of placing them near old buildings, such as those of Bellevue Hospital, in which the filth of years had been allowed to collect in floors and walls. The common practice of having the same physicians and attendants for both the old hospitals and the pavilions was also criticised by the committee.

Is Anteflexion of the Uterus a Cause of Dysmenorrhœa?—At a meeting of the London Obstetrical Society, October 5th, Dr. Herman read a paper on the above subject. On reading it, one may well ask whether there is anything certain in gynecology, for the author makes an elaborate and well-sustained argument against the prevalent view that anteflexion is a cause of dysmenorrhœa.

Few persons educated in New York have not heard the pathology of obstructive dysmenorrhœa graphically described, and the neck of the uterus compared to a gutta-percha tube, which is obstructed when bent at an angle. The illustration is simple, and at first thought convincing. The purport of Dr. Herman's argument against this view is as follows: 1st. There is no anatomical evidence that anteflexion causes any hinderance to the escape of menstrual fluid. 2d. There is reason to think that anteflexion is present in nearly half of all women who have not borne children. 3d. Therefore it is to be expected that anteflexion and dysmenorrhœa would frequently coincide. 4th. Dysmenorrhœa is, practically, as common when the uterus is straight as when it is anteflexed. 5th. Painless menstruation is, practically, as common when the uterus is anteflexed as when it is not. 6th. When dysmenorrhœa and flexion go together, the severity of the pain bears no relation to the degree of the bending. 7th. Dysmenorrhœa, associated with anteflexion, is frequently cured without straightening the uterus. 8th. There is no evidence that straightening the uterus invariably, or even frequently, removes dysmenorrhœa which is associated with anteflexion, and in which other methods of cure have been ineffectual. 9th. These facts show that the relation between anteflexion and dysmenorrhœa is not one of cause and effect, but of coincidence.

The paper of Dr. Herman was highly commended by the President of the Society, Dr. J. Matthews Duncan.

T. D. Fitch, Chicago, Ill.—The many friends of Dr. T. D. Fitch, of Chicago, will be glad to learn that his health has so far improved that he has announced himself as prepared to resume his practice. He has been more or less an invalid for over a year.

# Original Communications.

## ON ACIDUM BORACICUM AND CALENDULA OFFICINALIS, AND THEIR USES IN AURAL DISEASE.[1]

By SAMUEL SEXTON, M.D.,
NEW YORK.

In introducing these two remedies in their combined form for the treatment of aural diseases, I shall first give a separate account of the two drugs, and then present such suggestions for their employment as my own experience with them seems to warrant.

### ACIDUM BORACICUM,[2]

or Orthoboric acid, $B(OH)_3$, is formed by the union of the oxide of boron with water. This compound was first obtained by Homberg (1702), and may be prepared by adding hydrochloric acid to a hot solution of borax. The presence of this compound was observed in the water of the lagoons of Monte Rondo, in Tuscany, in the year 1774, by Höfer, a Florentine apothecary, and in 1815 an attempt was made to manufacture it from this source; it was not until 1828, however, that boric acid was thus successfully obtained. These lagoons now produce about three thousand pounds (1,400 kilos.) of boric acid daily. The commercial acid contains about twenty-five per cent. of foreign matter, which is separated by recrystallization from hot water. It is supposed by Wöhler and Deville[3] that boric acid as it occurs in the earth is derived from the decomposition of a nitride of boron. Boron is one of the elements which can combine directly with nitrogen, and the compound thus formed is decomposed by the steam of the lagoons into boric acid and ammonia. (Ammoniacal salts and sulphide of ammonium occur together with boric acid in the earth.) Boric acid is now found in various parts of the globe, and large quantities are obtained from the borax lake in California.

Boric acid crystallizes in shining, six-sided laminæ, unctuous to the touch, and belonging to the triclinic system. Its specific gravity is 1.4357 at 15° (Stolba). It is more soluble in hot than cold water; one part of boric acid requiring about six parts of water at 62° F., and about three parts of water at 100° F. It is easily soluble in alcohol, but insoluble in ether. It is mildly acid. This drug has been but little used in medicine as an internal remedy. Homberg, who gave it the name of *sedative salt*, claimed for it strong sedative powers, and, says Cullen,[4] "upon such an authority it was introduced into practice; and such is the favor of a new medicine, and such are the excuses so readily found for its failure, that it soon came to be much employed in France; and Mr. Geoffroy having found a cheaper method of preparing it, the government ordered, at their expense, that it should be furnished to all the medicine chests of the army and navy." After a thorough trial, the drug was abandoned as a sedative, and Cullen says: "that, even in large doses, this salt has no effect on the human body."

Boric acid is said to be destructive to the lower forms of animal life; thus cockroaches will not remain in the vicinity where it has been strewn, and it is believed to be inimical to bacteria. Within the past ten years, I am informed, it has been extensively employed for the preservation of fresh meats by shippers to foreign countries; meat which has been treated with a strong solution of the boric acid will not, it is said, undergo decomposition readily, and its contamination by flies, etc., is also thus prevented. During the Franco-Prussian war its antiseptic qualities were tested, it is said, with a view to its adoption for the preservation of the meat supplied to the army.

Toxic effects from the use of boric acid have been recently reported.[5] Mododowski, of Moscow, relates two cases in which the use of the drug was followed by fatal results: one, when a patient was tapped for a pleuritic exudation, and the cavity afterward cleansed by injections containing a five per cent. solution of the acid, some of which was allowed to remain; and another case, where a lumbar abscess was similarly injected. Nausea soon followed in both cases, with incessant vomiting and hiccup. General erythema occurred, first showing itself on the face. The temperature at first increased, and then sunk to 36° C. "The pulse became filiform, and cardiac paralysis supervened, with symptoms of utter exhaustion. The autopsy of the second patient exhibited punctated ecchymoses upon the anterior wall of the right ventricle, otherwise nothing remarkable. The mind of the patients was at no time clouded. These cases appear to show that probably the antiseptic action of a remedy may depend on properties at times poisonous, but further investigation is needed, as these two cases seem to be very impure."

The present writer has freely injected a saturated aqueous solution of boric acid through a small perforation of the drum-head into the middle ear repeatedly, without any unfavorable results.

Boric acid has been used in aural diseases for some years past, either instilled into the ear in solution, or blown in as a powder. It is not readily pulverable, requiring trituration for several hours before being reduced to an impalpable state.

### CALENDULA.

Calendula is the garden marigold of the English, the souci des jardins of the French, the ringelkraut or ringelblumen of the Germans, and the calendula officinalis of Linnæus. It belongs to the natural order compositæ, and several species are known. It is a native of Southern Europe and the Levant, and is well known throughout the United States and other countries as a garden plant, not only on account of the ornate character of its blossoms, but in many places also for its medicinal qualities. With us, and in England, it has not been so much used as a remedy as in France and Germany. According to Neale's[6] "Digest," which covers a period of twenty years of British medical literature up to 1877, no mention whatever is made of calendula. The only attempt to introduce it here in regular practice that I am aware of, was made some twelve years ago by Dr. Livezy,[7] of Philadelphia, who recommended it to be used in incised and lacerated wounds, and in contusions. It has been held in high repute, I am informed, in the domestic practice of New England, where it has been employed for a long time in certain forms of singultus.

Graumuller[8] says that formerly this plant was held in high esteem, and that the distilled water was used in inflammation of the eye, the fresh leaves for the hardened border of ulcers.

We learn from Strumpf[9] that the old physicians praised calendula as a cardiac tonic, emmenagogue, and diaphoretic, that, according to Tournefort, the leaves, flowers, and seeds can be used as a sort of solvent in stoppages, and in jaundice, scrofula, and difficult menstruation. The flowers were considered as a great remedy against malign diseases, especially the pest, in the form of their juice, or with vinegar poured over them. Marcellus Cumanus, Rondelet, Minderer, and Welch employed this remedy, and they likewise combined it with acetic acid as a preventative against headache. Matthiolus praised the plant as a remedy for cancer soon after Westring, who became acquainted with it in Sweden as a household remedy, brought it into general notice. Strumpf also states that through the activity of the fresh leaves, it has been sought to remove the callosed skin from the soles of the feet, the induration of tumors, or swellings and warts. The *unguentum calendulæ ex herba recenti* was considered of great service in excoriated nipples.

Murray[10] states that the recent leaves are more efficacious than the flowers; he found the former useful in removing corns and callosities of the feet, and the hard margins of ulcers when applied thereon. Internally, Murray says it was regarded as a sudorific. Hufeland[11] used calendula in ulcerated mammary cancer, both internally and externally, where it was found to diminish pain and secretion, but not to bring about healing.

Pitschaft[12] recommended that for scirrhus, the unguentum calendulæ of the Wurtemberg Pharmacopœia be employed.

In Germany, calendula once enjoyed a wide reputation; the herb itself, and the flowers, were used according to the pharmacopœias of Baden, Saxony, Schleswig-Holstein, and Hamburg. The following account of the drug from Strumpf is so complete, that I have made an almost entire transcript from his work. He says: "The endeavor to bring this seemingly powerful remedy into the confidence of the profession has never been particularly fortunate, probably because it was brought forward with too great expectations. Its disagreeable, almost narcotic, balsamic-resinous smell, as well as its salty-bitter and astringent or harsh taste—qualities which characterize the fresh leaves and flowers, particularly the more acrid calices of the flowers—lead to the opinion that it has more or less prominent healing powers. The chemical analysis, however, does not confirm these expectations, although experience proves it to be tolerably diaphoretic, a mild laxative, and in some degree strengthening to the circulation of the abdominal vessels." G. H. Stoltcze,[13] of Halle, found in the leaves gathered in May, bitter extractive stuff, only a part of which dissolved readily, the rest with difficulty; a green-plant wax (myricin), albumen, gum, calendulin, mucilage, fibre; malic acid, together with the malate of lime; muriate and nitrate of potash, besides water.

Calendulin, a peculiar substance like gluten, forms a yellowish white transparent mass of firm consistency; is without taste or smell; insoluble in water, but with it swells up into a jelly. When it is combined with the other extractives it dissolves in water, and imparts to it the property of becoming gelatinous when cold. It is readily soluble in alcohol, in caustic, in hydrated alkalies, and in strong acetic acid; insoluble in ether and the ethereal oils. It undergoes a chemical change with the oxides of iron and with tannic acid.

The extract of calendula is prescribed in doses of from four to thirty grains, and even more, two to four times a day. It is employed in the form of pills and mixtures; externally, a solution is used for saturating bandages, and, when combined with lard, as a salve. The bruised flowers are given in doses of one or two scruples, in powders or pills. The fresh or dried flowers, and also the plant itself, in infusion or decoction, are given internally, and they are also employed for injections, for bathing, and for bandaging—with fresh butter they are made into a salve. The *liquor florum calendulæ* is made from the flowers which have been thrown fresh, without being bruised, into thin flasks holding four to eight ounces, carefully corked, and, during the warm season, allowed to hang in the open air on the limbs of trees in such a way that they are exposed to the sun as much as possible. After some time a fluid separates itself, which must be poured off and preserved, tightly corked. According to experiments reported by Apothecary Stickel, of Jena, in 1836, the fluid that came from the flowers treated in this manner had a slightly acid reaction; later, the acidity increased and the fluid had a disagreeable smell, an unpleasant taste, and appeared cloudy. After eight weeks, about six ounces (German) of juice had separated from one and one-eighth pound of the flowers. The process of fermentation still continued, and its surface was constantly covered with mould; it was, therefore, not yet ready for use. After the mould had ceased to form, the fluid underneath showed no further changes; it was then dark yellow, had a mild, balsamic smell, somewhat penetrating, a sharp spicy taste, an acid reaction, with a specific gravity of 1009. In time, a mealy precipitate appeared. On distillation, an ethereal oil, together with acetic acid, was produced. The residue contained a soft resin, extractive, albumen, gum, mucilage, fibre, a great deal of chloride of potash, a little phosphate and malate of lime, but no calendulin.

The recommendations of calendula in cancerous troubles are received with some grains of allowance by Strumpf, who says that they are for the most part so nullified by the use of other remedies, or rest in other cases on such uncertain observations that they do not withstand the slightest criticism. Westring[14] thus exhibited calendula in cases of cancer of the breast and uterus with rennet (Kalberkroff), opium, chloride of gold, and charcoal. Rust exhibited it in cancerous tumors with oxide of iron, with the chloride of mercury, with sulphuretted antimony, conium, and cherry-laurel water. In the Kottbus's case of scirrhus of the breast, described by Rudolph,[15] Strumpf expresses doubts as regards the truth of the diagnosis, for the swelling of the tumor described there was soft and painless, and, besides this, he used internally the carbonate of iron, and externally the acetate of iron. Schneider's accounts

of cases are so general, and the descriptions are so superficial, repeating themselves frequently after so many different remedies, that they lose all credit. Fehr has found the plant of great value in all cases of scirrhus, giving from two to six drachms of the extract within twenty-four hours. Stein, of Weinheim, found it only useful in cancerous affections of the skin, using the decoction of the fresh calendula, with milk or water, by the cupful, or the juice of the plant in an aromatic water or in pills, together with bathing the parts with the decoction, bandaging, and the application of the salve—these allayed the itching and removed the smell. The salve caused some burning, which afterward disappeared. It must not be forgotten that Seibold and others looked for similar results in vain.

Ockel[16] praises calendula in hypertrophy of the womb; he gave half an ounce of the extract, with as much Glauber salts, in six ounces of water—a tablespoonful four times a day. Muhrbeck,[17] of Demmin, used the extract (four grains given five times a day) with good results in chronic vomiting, and Carter used it in like manner with similar results. De Camp,[18] of Lauenburg, administered, with advantage, four grains every two hours in a case of spasm of the stomach, attended with such excessive irritability that every remedy was immediately rejected. Schneider,[19] of Fulda, praises his liquor calendulas as an excellent remedy in stopping hemorrhage and healing fresh wounds.

If the profession in this country and in Great Britain have given calendula but little attention during the past quarter of a century, it has not been the fault of homœopathic writers, to whom, I regret to say, we are indebted for most of the recent literature pertaining to this valuable drug. Hughes,[20] one of the most prominent of that school, states that this plant owes its place in their materia medica to its power as a *vulnerary*, and that it is rarely given internally. It is recommended as having "a most beneficial influence over wounds, especially incised wounds, promoting union by first intention, or, where that is impossible, favorable cicatrization with the least possible amount of suppuration."

"The United States Dispensatory," twelfth edition, 1865, says: "Calendula is at present very seldom, if ever, used in regular practice, but it was formerly much employed in medicine. It was thought to be anti-spasmodic, sudorific, deobstruent, and emmenagogue, and was given in low forms of fever, scrofula, jaundice, amenorrhœa, etc. Both the leaves and flowers were used, but the latter were preferred, and were usually administered in the recent state in the form of tea."

"The National Dispensatory of the United States," 1879, gives a more complete account of the drug than the authority above cited. It also refers to its former employment in medicine, both internally and externally, and states that a saturated tincture of the flowers is said to promote the cure of contusions, wounds, and simple ulcers.

In France, calendula would seem to be employed to some extent in regular medicine at the present time. Cazin,[21] in his treatise, says of calendula: "In France it is cultivated in the gardens, and grows naturally in the southern parts of the country. All of the plant is used in medicine. The flowers are gathered during the entire summer, and the plant as long as the season remains pleasant. In drying, the plant becomes extremely light and fragile, and loses its fragrance; nevertheless, on being crushed by the fingers, a slightly aromatic and not disagreeable odor is perceptible, and it has a slightly bitter taste when chewed." Although the plant is found in commerce in the dried state, Cazin recommends the use of it only when fresh, as the drying process deprives it of nearly all its virtues. The flowers are sometimes used to adulterate saffron, and it is also employed as a coloring matter for butter. The plant, which is a native of the South of Europe, has been successfully cultivated everywhere.

Peyrilhe regards it as slightly narcotic. He has employed it in amenorrhœa, hysteria, chlorosis, jaundice, chronic enlargements of the abdominal viscera, scrofula, and intermittent fevers. Cazin has seen a decoction made from the fresh leaves of the plant and wild hops used with success in scrofulous affections. The patient at the same time took daily, two hours before breakfast, 120 to 180 grammes of a mixture consisting of equal parts of the juice of the plant and white wine.

Muhsbeck[22] is cited by Cazin as having used, with satisfactory results, an extract of the plant in doses of twenty centigrammes, given five times a day, in a case of chronic vomiting, of four months standing, in a woman, twenty-one years of age. He also used the drug successfully in other cases of chronic vomiting, and in one of them an ulcer of the womb was thus cured at the same time. Carter[23] also employed calendula with good results in chronic vomiting. The plant has been also used in the treatment of cancer,[24] and the extract, given in doses of fifteen centigrammes, every three hours, has been found useful in cases of pyrosis accompanied by vomiting.[25] Cazin has seen anasarca, following prolonged intermittent fever, in a woman living in a marshy district, cured in fifteen days by means of a simple infusion of the fresh flowers (twenty grammes to one litre of water) taken in a dose of one litre daily. The remedy produced free diuresis, and a considerable enlargement of the spleen disappeared at the same time. The decoction of the fresh flowers of calendula and of broom (a handful of each in a litre of water) taken in glassful doses every morning, fasting, has been successfully employed in dropsy, jaundice, and engorgement of the abdominal viscera, etc. Vitet finds an infusion of the flowers useful in amenorrhœa, and Schroeder believes it to be as efficacious in these cases as saffron. Cazin informs us that, popularly, a concentrated decoction of calendula and mugwort is employed as a vaginal injection, to bring about delayed menstruation. Chrestien, of Montpellier, introduced an injection of an infusion of calendula for the treatment of the os uteri. Cazin has himself applied with advantage the plant, reduced to a pulp, upon scrofulous ulcers and tumors. He has also found it useful when applied to callous ulcers, the induration becoming manifestly softened by its action. He has, moreover, used it with good results, following a popular practice in chronic ophthalmia, when decided irritation of the conjunctiva did not contraindicate its use. His greatest success, however, in

the use of the drug, was in cases of chronic palpebritis and scrofulous ulceration of the eyelids. Hecquet found the fresh leaves of the plant crushed upon warts, caused their disappearance. The flowers macerated in vinegar are, however, more efficacious, says Cazin, for this purpose. Dubois, of Tournai, has witnessed its successful action upon warts, in the case of an infant.

According to Cazin, the souci des champs, or the wild calendula, resembles very much the calendula of the gardens, but does not grow so high as the latter, and its flowers are not so large or so numerous; they are of a lighter yellow color. The blossoms open about nine o'clock in the morning and close about three o'clock. Its properties are similar to the cultivated plant, and the Germans generally employ it for the same purposes.

"If," says Cazin—in concluding the interesting article on calendula from which I have so liberally drawn—"if the ancients have exaggerated the virtues of this plant, the moderns have neglected it too much."

From the foregoing cursory glance at the literature concerning calendula, it is evident that for the past hundred years, or more, it has been regarded as a valuable remedy in disease. As has been seen, its reputation has been a variable one, and, without doubt, it was, in former times, much vaunted as a cancer cure, both within and without the profession, by some whose disinterestedness and intelligence may well be doubted. We must, therefore, in delving into the accumulated literary rubbish respecting the uses and value of this plant, endeavor to separate the wheat from the chaff.

As an internal remedy, calendula does not seem to be employed anywhere at the present time, unless it be in France. Its external use for the past twenty-five or fifty years has been very considerable among homœopathic practitioners, but before their time it enjoyed a great reputation in medicine. We have seen above, that calendula has been employed in almost all departments of surgery with success, and it is a matter for wonder that its healing virtues are not more generally recognized at the present day.

The therapeutical value of the different constituents of calendula has not been ascertained as yet. The glucoside, calendulin, which was a discovery of Geiger, is a neutral body, without taste or smell, and it is probably the cause of the cloudiness which is sometimes present in the tincture. The gummy, mucilaginous properties, which are bland and non-irritating, doubtless afford some mechanical protection to wounds.

It may be well to state in this connection, that it is said (Nat. Disp., 1867) that the flowers of *tagetes erecta* are used as a substitute for calendula; "that most of the *fluid extract of calendula* at present in the market is really obtained from the species named (tagetes erecta) and from tagetes patula. These two plants are indigenous to Mexico and tropical America, but are often cultivated under the names of *French* or *African marigold*." Cazin, in speaking of tagetes patula, says the plant is reputed to possess qualities of a harmful nature, which render its use unsafe, and that, although virtues are claimed for it, they need to be confirmed by experience. It will be well, therefore, for those who hope to obtain the true action of the drug, to select a preparation for use, the purity of which is guaranteed.

Nearly all of the writers that I have consulted on the subject, both ancient and modern, agree on one point, namely, that the fresh plant shall be employed in all cases. In my own experience in the use of the drug, I have always employed the alcoholic tincture from the fresh flowering plant. This tincture is liable to become turbid if exposed to a low temperature, but usually clears up again on being heated.

My attention was first called to the external application of this drug several years ago, by my friend and neighbor, Dr. Piffard, who appears to have used it for a number of years as a dressing after operations, in preference to ordinary carbolic listerism.

### THE EMPLOYMENT OF ACIDUM BORACICUM AND CALENDULA IN THE TREATMENT OF AURAL DISEASES.

My own observation soon convinced me that the action of calendula on granulating and suppurating tissues, and its prevention of suppuration when used upon recent wounds, would render it a valuable remedy in aural diseases, and I, therefore, subjected the drug to a thorough trial in my practice. The results obtained have been entirely satisfactory. The first trial of it was made with a thin salve, prepared by mixing one drachm of the tincture with three of fluid cosmoline, the alcohol being driven slowly off by the use of a water-bath. This preparation, however, was found not to be satisfactory where dryness of the parts was required, and an attempt was afterward made to saturate absorbent cotton-wool with the tincture, and then evaporate off the alcohol; owing to the gummy nature of the residue retained in the wool, even when a comparatively small quantity of the tincture had been employed, the absorbent quality of the wool was in great measure lost, and this preparation was soon abandoned. It now occurred to the writer that pulverized boracic acid could probably be availed of as a vehicle for carrying the calendula into the ear and retaining it there, and, on trial, the plan proved to be entirely successful. This mixture is made of equal parts by weight of tincture calendula and finely powdered boracic acid, as follows: Evaporate the calendula down in a water-bath, at a temperature of about 150° F., to a pasty consistency, and then mix with one-half of the boracic acid: evaporate to dryness, add the other half, and triturate.[26] I do not always employ this preparation in its full strength, but frequently find it sufficiently strong of the calendula when reduced by the addition of more or less pulverized boracic acid.

The local action of both of these remedies on suppurating surfaces, seems to be somewhat similar: they are, perhaps, antiseptic, and it is their nature to promote healing; by means of their action secretions are checked, odors are stopped, and healthy granulation promoted. In some otorrhœas the boracic acid may be employed as a dressing, and will not be found so heating as cotton-wool. In this way a light crust is sometimes formed over ulcerating or secreting surfaces, protecting the former while cicatrization goes on, and preventing the latter, when retained, from macerating the neighboring parts and from undergoing decomposition.

In by far the greater number of cases of suppurative otitis media, I prefer these drugs in combination. Their range of application is thus very extensive; when used in traumatic rupture of the drum-head, and in the myringitis accompanying perforative inflammation of the middle ear, the results have been most gratifying. In ulcerative inflam-

[26] This preparation has been made for me by Messrs. Caswell, Hazard & Co., New York.

mation of the external auditory canal of children, especially in the neglected cases among the poor, where the discharge is sanguineous, purulent, and highly offensive, the mixture is very efficacious.

After the removal of polypi, as soon as the bleeding has been arrested, it is sometimes useful.

The powder may be introduced into the ear through an aural speculum, or it may be blown in with a small insufflator.

In acute cases, the powder should at first be applied with great care, for in some instances it is not well borne at the beginning of the attack.

In nearly all cases, the discharge may be expected to lessen under this treatment; and, when odor is present, its disappearance may be confidently expected to take place very soon.

## REMARKABLE AUTOMATISM IN AN EPILEPTIC.

By EDWARD C. SPITZKA, M.D.,

NEW YORK.

On December 5th, I saw, through the courtesy of Dr. Fuhs, of Williamsburg, a most unusual form of epileptic disturbance. At the time of my visit, the patient had an "access;" he was lying on his back, with his head in almost tetanic extension; the eyes directed to the ceiling, and fixed, without deviation; the pupils in maximal dilatation, so that the iris was reduced to a mere fringe; and the muscles of the larynx in extreme tonic contraction, the cartilages standing out in bold relief, and immovably fixed. The respiration was stertorous, and about twenty-eight per minute. After being in this state ten minutes, his arms underwent a slow tonic contraction, the fingers spreading and the hands crossing; the patient began to tear at his larynx with such force that, if not prevented, there is no doubt that he would have succeeded in tearing its cartilages asunder, if not lacerating the throat altogether. These movements had every element of skilful co-ordination and of purpose, but the patient was absolutely unconscious, and his pupils remained in the same condition as in the first stage. Prevented from tearing his throat, the patient now moved his jaws, regularly opening and shutting them with a loud sound, and with the purpose of biting—he brought his fist up to his mouth, and would have bitten it if not prevented. His expression now became frightful; it was an old story to the relatives and bystanders, and their statement, "that he looked like nothing so much as a wild beast driven to the verge of savage ferocity," describes his appearance better than any technical account could do. While three persons were controlling the rest of his body, his wife held his head, to prevent him from snapping at the hands of those holding his arms down, and the patient *put out his tongue, like a tentacle, to feel where a portion of his wife's hand was available for biting.* These movements were as well coordinated as those of an ant-eater when seeking insects with his tongue for the purpose of drawing them into his mouth, and the purpose, if it can be called such, was as manifest in this man's case.

The "biting spell" passed off in about five minutes, and now the patient began kissing the air with much unction, and with as regular a rhythm as he had previously shut his jaws. Again he had a biting spell, of slighter intensity, and during its progress I made him inhale about thirty drops of amyl nitrite, all of which seemed necessary to insure the physiological effects of that drug. He became more violent for a few seconds, but after the short spell of excitement ensuing he became relaxed, and lay quietly in bed. After a brief period of rest he began singing, in a cracked voice and with thick speech, discordant snatches from various German and English songs. With these he also began to improvise rhymes, and it was noteworthy how quickly the still imperfectly conscious patient formed rhymes and corrected improper ones. As he went on rhyming, I found that his rhymes could be anticipated in many instances. I subjoin a sample from memory:

"Oh with my little fat belly,
I wish I could fill it with jelly;
I wish I could go to court,
Oh boys, let's hold the fort.
Then when we all get through,
Please don't you look so blue;
And then when we are done,
We'll surely have some fun;
And won't we all be good,
That's just what we all should."

And so on for hours, on occasion, with variations. He could not be induced to enter into conversation, nor to take any notice of his surroundings. He was evidently in a post-epileptic mental state, resembling those described by Samt * and Falret, and consciousness was only a little less blurred than during the spasmodic stage. It was observed that, immediately on giving the amyl nitrite, the iris became more visible, the pupil contracting by about one millimetre. The amyl was administered in a second spasmodic attack recurring about half an hour after the first attack. Resolution occurred after its use, but its pupillary change was less decided than on the former occasion.

The patient's cranium had a vicious conformation, and the face was asymmetrical, the lower jaw being "drawn" toward the left. Dr. Fuhs, who had always regarded the psychical and motor phenomena exhibited by this patient as of an epileptic character, informed me that since the 8th of November, when he took charge of the patient, the attacks had gradually increased in severity—about fifty attacks had occurred in the month. At first the patient was rational and conscious in the intervals, but for the last six days he had not returned to complete consciousness, except on one occasion, and then, on the testimony of his relatives, he was somewhat confused. The attacks themselves had changed in character. At first unilateral tonic spasm of the left side occurred, the patient becoming unconscious, and denying all knowledge of the fit on awakening, but complaining of soreness on the affected side. Dr. Fuhs saw him in these attacks, found absolute dilatation of the pupil, and the duration of the fit to be about three minutes. Sometimes generalized spasms set in during the period of unconsciousness. The pulse was never observed to be over 80, nor the respiration to be abnormal, by the doctor. The latter had repeatedly noted the spasms of the larynx, the "biting spells" and spasms of the diaphragm, as well as a soreness and a presumably reflex stiffness (contracture) of the nuchal region. He had also ascertained that the patient had been epileptic six years, and that for one period there had been unconsciousness for two months, the patient resting on his head and heels, and in tetanic rigidity for that period, being treated for "cerebro-spinal meningitis." Dr. F.'s inquiries, however, showed that there had been no grounds for such a diagnosis at any time. The

* Archiv. für Psychiatrie, vi.

mother is asserted to have epileptic attacks, and one brother has similar attacks, on recovering from which he makes indecent assaults on any female he encounters, and has made such on his own mother.

The mental condition of the patient in the interval presents nothing of novel interest; in this respect the history is almost a paraphrase of the histories of pre-epileptic, post-epileptic, and intervallary *moria* described by Falret,* Samt† and myself.‡ The automatic spasms of the character related are exceedingly rare. The only similar case of which I can find a record is one recorded by Kiernan,§ where the laryngeal symptoms and other phenomena presented by an epileptic were such as to resemble hydrophobia. The laity undoubtedly would on first sight have considered the patient whom I saw with Dr. Fuhs a case of hydrophobia. His "biting spell" corresponded to the traditional and, I need not add, incorrect views held of that disease by popular lay and medical writers.

The occurrence of spasms simulating the co-ordinated movements mediated by the oblongata and other lower brain-segments, seems to me to confirm Meynert's hypothesis, that the essential phenomenon of epilepsy is cerebral anæmia, with relative hyperæmia and functional excitation of lower centres.

It may seem a truism to make the special statement, that there are no grounds for assuming a "localized lesion" in such a case. But as such a disclaimer is rendered necessary by the extreme length to which the localization theory is carried by dogmatic teachers, under the heading of "early diagnosis of epilepsy," I will make it. While the present publication of the case is merely provisional, I will briefly state that, aside from the symptoms mentioned, all the somatic and mental signs were those of true epilepsy. The speech of the patient had always been thick, and he had given vent to morbid ideas concerning his wife since she had known him, a period of nearly three years.

---

AT THE FUNERAL OF THE DEAD DOCTOR—WHAT IS SOMETIMES HEARD FROM THOSE ATTENDING.—"So G—— is gone! Too bad, isn't it?" "Yes; what was the cause of death?" "Meningitis from overwork." "Specimen obtained?" "Yes; will be presented at Pathological Society. Come and discuss it." "Well, G—— was a good fellow, but did not seem to succeed very well. Did he leave anything?" "Not much; understand his library will be sold for benefit of widow and children." "Indeed! some volumes quite valuable." "When is auction to be (thinking of a set to be completed)?" "Who is to have his place at the hospital?" "Oh, that was arranged when he was sick." "F—— will surely apply." "Too late; place belongs to our college." "Who attended him?" "No one in particular; his medical friends dropped in occasionally." "Was he conscious at any time?" "Yes; promised his skull to me." "Got it?" "No!, Widow objected." "Who writes his obituary?" "The man who has his place." "Speaking of meningitis, I had a patient ——" (commences to recite case in detail; while so doing, listener, interrupting, suggests that the funeral has commenced).

## A PHENOMENON OF PARTIAL MORPHIA-NARCOTISM.

By HENRY E. JONES, M.D.,

PORTLAND, OREGON.

As a practical clinical fact, I desire to call attention to a symptom of partial morphia-narcotism to which no written reference has yet been made that has come to my knowledge, but which may not be new to the experience of old practitioners. Again and again have patients complained after taking only mild anodyne doses of morphine, by mouth or syringe, of a sensation of numbness of foot or hand, sometimes of one arm, and occasionally of one side of the body. This they compare to the common sensation of the limb being "asleep," though the painful "awakening" is absent.

The side on which pressure during sleep exists, is the one generally complained of. Hence the patient is not a little distressed at times, being convinced that he is experiencing the premonitory warnings or first symptoms of paralysis. When symptoms of brain lesion or monolateral amaurosis are present, the practitioner is not unlikely to be himself deceived, and a victim of hysteria is sure to make convenient use of this ambiguous sensation. Male patients not infrequently make complaint of the same numbness. As to the *rationale* of this phenomenon it is probable that it is of central origin, and results from the cerebral anæmia to which narcotism is attributed. Its occurrence from pressure during sleep may be due to dilatation of the capillaries and venous stasis of vaso-motor origin.

November 22, 1881.

## DISLOCATION OF ACROMIAL END OF CLAVICLE DOWNWARD AND BACKWARD.

By FRANK B. EATON, M.D.,

PORTLAND, OREGON.

In the fourth edition of Hamilton's "Fractures and Dislocations," it is stated that only three well authenticated cases of dislocation of the acromial end of the clavicle downward are on record. I give the history and treatment of the only one I have ever met with, recently under my care.

The patient was a ship's carpenter, about fifty-five years of age, who gave the following history: Several years previously he had sustained a fracture of the right clavicle at the junction of its middle and outer thirds, from which he made a good recovery.

Two months ago, while at sea, he one day strained himself working and lifting, but was certain that he received no blow or violence.

He noticed nothing beyond this until the night following, when he was awakened by a violent pain in the right shoulder, which had never left him, depriving him of rest during the greater part of the night.

At the same time he lost the use of his right arm. He soon noticed that certain motions produced a loud "clicking" sound, plainly audible to himself and those about him; several of his mates testified to having heard this sound. On examination I observed that he carried the right shoulder forward and inward, giving him the appearance of being round-shouldered.

Comparison with the other shoulder showed that the only deformity was a slight prominence over the

acromio-clavicular articulation; there was no redness. Any motion of the arm gave him considerable pain, and it was only with great difficulty that I could carry the right hand to the forehead. Palpitation discovered that the articular surface of the right scapula was unoccupied, a condition much increased by carrying the arm forward and to the left, the relative position of the outer end of the clavicle being downward and backward.

Reduction was readily accomplished, by standing behind the patient, and gently, but forcibly, drawing the shoulder outward and backward. A bread bandage was then applied to the chest, high up, including the scapula, and the arm itself bandaged to the side. The patient expressed himself as much relieved, laxation did not recur, and in two weeks the patient returned to his work aboard ship, gradually recovering the use of his arm.

The etiology in this case is so obscure as to naturally create doubt as to the correctness of the diagnosis, for the three recorded cases were, *as far as ascertained*, "produced only by a force which has acted directly upon the top of the clavicle." No physician who examined this case, however, would for a moment hesitate to give a similar diagnosis. There was no overriding by the acromion process, the ligaments apparently not being all ruptured, as would occur from violence directly applied. The patient's age, history of fracture of clavicle, the carrying of timbers on the shoulder incidental to a carpenter's labors, would account for the stretching and partial rupture of the acromio-clavicular and coraco-clavicular ligaments, and, during the relaxation of sleep, the motion of the vessel might readily produce a dislocation.

November 22, 1881.

## DISORGANIZATION OF THE LUNG, AND EVENTUALLY RUPTURE, WITH FATAL HEMORRHAGE INTO THE PLEURITIC CAVITY.

By J. O. SKINNER,

CAPTAIN AND ASSISTANT SURGEON U. S. ARMY.

I NOTICED by THE RECORD of October 29th, that Dr. Watson presented to the New York Pathological Society a specimen of lung-rupture from violence. This report reminds me of a case which occurred last year (1880) during my administration at this post. I have, therefore, had it copied from my case-book and send it to the MEDICAL RECORD in the hope that some of the points in its clinical and pathological history may be interesting to the profession.

Private Thompson was admitted into Post Hospital, October 5, 1880. The history of his case, as given by himself, was connected with both malarial and syphilitic poisoning. There was no evidence of existing syphilitic trouble other than that cachectic and prematurely aged appearance incident to chronic malaria, syphilis, etc. He complained of a cough, but expectorated little or nothing. His treatment consisted principally of tonics and liberal diet, with an occasional dose of cough mixture. His condition remained the same for several days, when he commenced to improve, and was able in a short time to leave his bed, take moderate exercise, and, apparently, enjoy his food. The history of his case, however, in connection with his cachectic appearance, induced me to recommend his discharge from the service on a certificate of disability, which recommendation was being acted upon at the time of his death. He had just returned, October 14th, to the hospital from the company barracks, whither he had been to make certain inquiries concerning his transportation to San Francisco, and was standing on the hospital porch conversing in a quiet way with a comrade, when he suddenly ceased talking, fell over, gave one or two gasps, and was dead.

*Autopsy*, one hour after death.—Brain firm, but anæmic; light subarachnoid effusion. Heart: some hypertrophy of right ventricle, which was empty; no valvular trouble. Lungs: right lung normal, excepting an unusual number of surface pigmentary deposits; left lung contained near its root and centre a large infarction, and a rent, two inches in length, on its anterior surface, three inches from its internal margin, and immediately anterior to the infarction, with which it communicated. The lung presented a shrivelled, dark, and atrophied appearance, and was completely collapsed. The parenchyma of its upper and external parts seemed intact. The pleural cavity contained a large quantity of fluid and clotted blood of a mahogany color, which was lying around and upon the lung. The cavity, when opened, presented quite a peculiar appearance, as the clot possessed the size and shape of the lung itself, with no pulmonary tissue in sight. The parenchyma was everted through the rent and had, in this locality, that dark, grumous, semi-solid appearance so characteristic of splenic dissolution in typhoid condition. Both the infarction and rupture communicated with the pulmonary artery. The infarction was superior and posterior to the artery, was laminated, and was contained, in part, in what seemed to be a fibrinous sac. It was about three inches in diameter, its layers were concentric, and its central parts presented here and there a grayish or yellowish, dense, inelastic structure. Between its fibrinous sac and its distal peripheral surface, there seemed to be a commencing metamorphosis, possibly puriform liquefaction, in the form of a grayish, viscid, gelatinous material. The strata of this central mass were so arranged as to overlap each other, and seemed to have been deposited at irregular intervals, although there was no fluid material between these layers. They would peel or break off from the mass like the layers taken from a raw onion or a cooked beet. At the periphery of this mass, adjacent to the pulmonary artery, were three or four coagula evidently of more recent deposit and growth. These were almond-shaped, filbert-size, and disconnected from both the artery and infarction proper. The walls of the pulmonary artery at this point, if any existed, could not be distinguished, but what seemed to be their degenerate coats, or the remains of the primary focus of the infarction, was present in the form of a brittle, glistening, though scarcely calcareous, deposit on the proximal (cardiac) surface of the infarction. The aorta also presented this condition. No examination was made for venous thrombosis; kidneys, liver, and spleen not examined.

*Remarks.*—As there appeared no evidence of heart disease, external suppuration, or ulceration, it is reasonable to presume, in connection with the syphilitic history and cachectic appearance on admission of this case, that this infarction originated from embolism consequent upon either a detached portion of degenerated (syphilitic) arterial tunic, or a coagulation of a sluggish circulation with a decrease of heart energy. The marasenic, or atrophic, theory is scarcely tenable, however, in the face of more favorable facilities to be found in the size and site of

extremity arterioles; hence the belief in the specific origin, in the form of arteritis, of this infarction.

With even a very limited or circumscribed zone, originally, of a diminished blood-supply, there exists in "Rokitansky's" theory a ready explanation of the probable increase in the number of diseased districts where occlusion occurs. "Occlusion of the minutest arterial branches of the lung and its capillaries causes collateral hyperæmia, which results in hemorrhage and exudation" (Rokitansky). As this theory is not accepted by Niemeyer, Cohnheim, and others, it is advisable to look for a more logical explanation of the existence of so large an infarction, particularly when it is remembered that there was no evidence in this case, during life, in the form of sudden and extreme dyspnœa, to sustain the belief that the pulmonary artery had been seriously and suddenly, even though partially, obstructed. The more recent and reliable observations of Ludwig, however, confirmed by Cohnheim, have demonstrated that "tension within the artery below the point of constriction is diminished, since a liquid flowing through a narrow tube loses more of its impetus than in flowing through a wide one; but we must infer from this that when an artery is constricted, the contents of the capillaries are lessened, and that the parts they traverse grow paler. The sluggishness of the stream thus produced in the capillaries rather has the effect of allowing the heavy blood-corpuscles to collect and become crowded together. Now, as two or more blood-corpuscles, if brought into contact, are apt to become permanently adherent, the blood itself can form a plug capable of closing the capillaries. Such an occurrence, which converts the capillaries into blood-appendices to the artery, must cause an increase in the internal pressure."

Niemeyer further writes: "Let us add that, in consequence of the pressure, which, after the stoppage, is as severe in the capillaries, with their delicate walls, as in their different vessels, a rupture of the distended walls and an escape of blood ensue. This furnishes a simple and entirely satisfactory explanation of the origin of the hemorrhage, as well as of its limitation to the region supplied by the occluded artery. The utmost that can be advanced against the accuracy of this explanation is, that the artery leading to an infarction not only is narrowed, but entirely closed. Such an objection, however, is untenable. The infarction of an embolus, which we find usually takes place at the bifurcation of an arteriole, very rarely produces absolute closure of it at first, but merely causes in it more or less obstruction. Afterward, when the infarction has become established—an event requiring but little time—fibrine is deposited upon the embolus, and closure of the vessel becomes complete."

An embolus, once arrested, may cause additional ones by detached fragments from the parent one, or, indirectly, by a retardation of the blood-current, in consequence of the resistance or obstruction it creates. An infarction, once established, may also occasion a collateral passive hyperæmia by mechanical influences, and thus assist in the reproductive process. The opinion is, therefore, held that the infarction was the product of several, yet similar, factors, operating, it is true, within a limited area. This process was restricted to these limits at first by the arteriole facilities in this locality, and subsequently extended by the increasing obstruction that distended or ruptured capillaries offered to collateral circulation. Surely, no such occlusion, even though partial, of so large a vessel as the pulmonary artery, or a sudden escape of so much blood as indicated by the proportion of this infarction, would occur during life without some extreme disturbance of the lung or brain functions, in the form of alarming dyspnœa or syncope.

There was no characteristic sputum; in fact, little or no expectoration of any kind occurred during the course of the disease.

The cough, during the few days it lasted, was of a nervous, hollow character, and occurred in paroxysms more marked when talking. The peculiar and unusual avoidance of bronchi by so large an infarction, with its collateral hyperæmia, was evidently remembered by Hertz, in his admirable article on hemorrhages from the lungs, when he writes: "As we have already mentioned, many a case of hemorrhagic infarction wholly escapes diagnosis, and is only a post-mortem discovery; as, for instance, when it is small-sized, or is situated in the interior of the lung, or when the blood cannot be expectorated, owing to occlusion of the bronchial branch connecting with the infarction."

The occasion of these remarks has been, not so much the infarction as its results, *i.e.*, lung-rupture.

No authority, at present accessible, alludes to any such accident, and it is regarded as an unusually rare occurrence. The lung-tissue, through which the stream broke, was doubtless already weakened by a structural change consequent upon a collateral passive hyperæmia, with or without exudation, and must have, eventually, resulted, by gangrene or hemorrhagic infarction, in disorganization.

When, therefore, his diminished strength had so far progressed as to favor, at any moment, a structural disintegration, and the tissues involved failed to receive, in consequence of their surface proximity, that degree of mechanical support previously obtained when confined to the interior of the lung, the solution of continuity occurred with a fatal result. The circumstances attending his last moments were far removed from any unusual physical or mental effort, and the result, if at all, hastened, can only be explained by the assumption that the infarction proper, with the several smaller coagula, in consequence of the erect position, may have, by gravity, increased the obstruction of the artery to that extent as to direct the force of the current toward or against this susceptible tissue.

Wagner remarks on the collateral circulation of parts obstructed by embolism, that "the collateral circulation already established can thereby be interrupted so that primary coagulum gradually grows toward the heart."

It is to be regretted that the specimen was not preserved; but, as "pulmonary apoplexy" is such a common occurrence from hemorrhagic infarction, it was not known at the autopsy that hemorrhage into the pleural cavity, exclusively from infarction, was so rare.

Whipple Barracks, Prescott, Arizona.

---

Decrease in the Number of Physicians in Prussia.—According to the official "Medicinal-Kalendar" of Prussia, for the year 1881, there were, during that year, 8,336 physicians and 103 surgeons. In 1880 there were 8,437 physicians and 119 surgeons. The decrease is, therefore, 117. The number of inhabitants of Prussia is 27,251,067, and there is, consequently, only one physician or surgeon to about 3,200 inhabitants.

# Reports of Hospitals.

## WOMAN'S HOSPITAL, NEWARK, N. J.

SERVICE OF EDWARD J. ILL, M.D.

(Reported by THOS. DARLINGTON, M.D., Assistant Surgeon.)

### ATROPHY OF THE UTERUS TREATED BY ELECTRICITY.

MARY B—— (clinical patient), native of the United States, aged twenty. Family history good. Menstruation appeared at the age of fourteen. Was regular for little over a year. She states that from the first she had fourteen or fifteen periods, each one lasting a day or a day and a half, with some slight pain at the beginning of the flow; but that they suddenly stopped, and that now she has not had a period for over four years. Has been somewhat annoyed with the "whites." She complains of weakness, headaches, cold hands and feet, and sometimes sharp pains in back and sides; she also suffers considerably from indigestion, pain after eating, nausea, etc.; has no appetite for food.

The appearance of the patient is that of a girl of fourteen or fifteen years of age. The external organs of generation are well developed. Internally, the vagina is normal, but the cervix is very small and hard, while the uterus measures only about one inch in depth.

For constitutional treatment she was given a powder containing potass. brom., guarana, and quin. sulph.; while locally, electricity (faradic current) was used. One pole was placed in the cervix, while the other was placed sometimes over each ovary or the uterus, and sometimes over the lower part of the sacrum.

From April 11th to about the middle of June, seventeen applications were made.

On June 15th and 16th she menstruated for the first time in four and a half years. From that time until October nothing was seen of her, as she did not come to the clinic.

October 17th.—States that her periods have come regularly every four weeks, and lasted about a day each time. Upon measurement, the depth of the uterus was found to be two and one-fourth inches.

November 14th.—Her head does not trouble her so much; her breasts are somewhat larger, and has noticed this particularly as her dress has become considerably tighter.

At her last period, two weeks ago, the flow lasted two days, and the menstrual discharge was greater than ever before.

### LACERATIONS OF THE CERVIX.

Quite a number of cases have been operated upon for lacerations of the cervix; and all of them, with the exception of one, were attended with success. In this case only one side remained closed after the removal of the sutures, and the attending gastralgia, and other reflex nervous symptoms, persisted after the operation.

The preparatory treatment of most of the patients was the use of the douche twice daily—a gallon of *hot* water being used for that purpose—painting the cervix with tinct. iod. twice a week, puncturing the cysts, if any, with Buttle's spear, and the introduction of a glycerine tampon.

All of the operations were done *without ether*, neither was any opium or other anodyne used, and in no case did the patient complain of pain, nor were there any movements made on their part which would hinder the operator. The only complaints made were the uncomfortable feeling of stretching the parts produced by the speculum (the largest size Sims having been used on each occasion), and the tiresome position in which the patients were placed. Several of them were inclined to be a little hysterical and nervous after the operation, but, besides this, there was no after trouble, as there is after ether; though this is not the only point gained, for it also saves the danger attendant upon giving it, obviates the attendance of an assistant, saves the time used to put the patient under its influence, and also the trouble that operators experience when the patient vomits, it being impossible to continue an operation upon the uterus while this is taking place.

Two of the cases were operated upon near the menstrual period, and in both cases flowing took place while the stitches were in situ; but the results were just as good in these cases as in the others, the only difference in the treatment being that the sutures were left in two or three days longer.

## HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

CLINIC OF DR. LOUIS A. DUHRING,

PROFESSOR OF DISEASES OF THE SKIN.

### RECURRENT PEMPHIGOID ERUPTION.

THE patient, a young negress, about twenty years of age, has presented herself at the clinic from time to time for the last five years, being afflicted with a recurrent bullous disease of the skin. The character of the disease here exhibited is rare and of an anomalous form, which may bring it properly under the head of the so-called "pemphigoid eruption." The lesions consist of blebs, varying in size from a pin-point to a goose-egg, the average size being that of a hickory-nut or an English walnut. These blebs run an acute course in from three to six days, becoming distended with a clear fluid, which later becomes cloudy. They occur in different parts of the body, scattered about singly on the face, scalp, arm, neck, mouth, and vagina. In the last two places, after rupture, they might be mistaken for mucous patches. There is nothing peculiar about the blebs, except that they are more irregular in shape than the blebs of true pemphigus. Those on the chest are variously shaped, some being elongate or wedge-shaped; others are oval, especially those on the flexor surface of the forearm. They rupture sooner or later, leaving dark, lasting, pigmented spots.

The history of this case is long and obscure, and hardly necessary for me now to recount. The chief points of interest and importance connected with it are the irregularity of her menstrual function. There is no doubt but that the blebs are dependent upon the latter symptom. Sometimes a year will elapse without the appearance of any blebs. During this time menstruation will be more regular. Then, again, when menstruation is irregular or absent, they appear in numbers. There can be no doubt, therefore, that there is a direct connection between the eruption and menstruation, as, when her menses are irregular, the eruption is more profuse, and *vice versa*. The patient is, moreover, subject to vicarious menstruation, as on several occasions she has had a flow of blood from the ear. This fact in the history of the case is interesting, because by relieving the irregularity of menstruation

we may hope to strike at the cause of the eruption, and thus cure this very annoying cutaneous disease.

LARGE, FLAT PUSTULAR SYPHILODERM.

The patient, a man, about thirty-five years of age, exhibits a marked skin disease with striking lesions. According to his statement, the initial lesion of syphilis was received about four years ago. He first noticed a "small red pimple" on the right side of the penis, and this was later accompanied by a bubo in the left groin. He took medicine, he states, which arrested the process, and no other lesions showed themselves for nearly a year, when mucous patches appeared in the mouth and on the tongue. A year later he suffered with articular rheumatism, affecting the right ankle, shoulder- and elbow-joints. The great toe, also, of the left foot became swollen and violently inflamed.

Five months ago, a large ulcer appeared on the outside of the right elbow. This healed rapidly under internal treatment. After the remedy was discontinued, there soon appeared a new ulcer over the right wrist. This was followed by other lesions, until he had about a dozen on different parts of his body.

The history is one of syphilis, and we naturally relegate the cutaneous eruption to the syphilodermata. On the side of the face, at the angle of the jaw, there is now an ulcer about the size of a large olive, covered with a thick greenish crust. It is sharply defined, and possesses a dark red, somewhat irregular, and indurated border. Looking more closely, we may notice on the upper border a greenish yellow secretion, which soon dries and forms the peculiar stratified oyster-shell crusts. A similar lesion is noticed back of the ear, which presents an excavated, ulcerating surface, with but little crusting. The other ulcers present much the same appearances; they have that characteristic, sharply defined, "punched out" appearance which renders the diagnosis easy. The crusts of these ulcers were formerly called "Rupial crusts," but this term is fast going out of use, the disease being now generally known as the *large, flat pustular syphiloderm.* On the sacro-lumbar region we see a large scar, sharply defined, and looking as though it had been punched out. After six months the lesions which we have considered will, without doubt, ultimately result in such scars. The lesions of this syphiloderma are not very deep, and in this respect they differ from the gummatous syphiloderm. The patient when cured of this eruption will probably consider himself a well man, but he will, in all likelihood, come to us again some years hence, and the lesions will then probably be gummatous. The treatment is mainly constitutional, and consists of full doses, from ten to thirty grains, of the iodide of potassium. Locally, the oleate of mercury, from five per cent. to seven per cent. strength, may be used with benefit.

PAPULO-SQUAMOUS SYPHILODERM.

The patient before us, a man, thirty years of age, presents a well-defined eruption about the thighs, legs, hands, and feet, but which is mostly marked about the palms of the hands. The scalp is free, likewise the back, with the exception of a few disseminated papules on the back of the neck. The lesions on the thighs consist of flat, dark red patches, varying in size from a split-pea to a dime, rounded and irregular in form, slightly raised above the level of the surrounding skin, and covered with scanty yellowish scales. The lesions on the legs and feet have the same general characters.

On the palms of the hands, the eruption is evidently in a chronic condition. According to the statement of the patient, it has existed six months. We notice here variously sized papules covered with a yellowish, hard, or even horny exterior, due to the great proliferation of epithelial cells. Foreign matter has become mingled with it, which makes it present a greenish or blackish color. Here and there are fissures.

Between the second and third fingers of the left hand there is a papule which is eminently characteristic. It is about the size of a large pea, and is of a distinctly coppery color. We notice a similar lesion on the right hand. It is round, sharply defined, the edges being covered with adherent scales, and from the centre is issuing a scanty mucoid discharge.

The lesions over the legs are by no means characteristic, and here the diagnosis is not easy. It might be confounded with psoriasis, and in some cases it is almost impossible to differentiate the disease without going very minutely into the symptoms. Here, however, the copper-colored mucous papule on the finger is quite sufficient to distinguish the disease from psoriasis.

As for treatment, it may be stated that the disease is usually stubborn, both local and constitutional measures being required. I would advise for the internal treatment small doses of the biniodide of mercury, from $\frac{1}{24}$ to $\frac{1}{16}$ of a grain, together with iodide of potassium, from two to five grains, three times daily. Locally, after the dry epithelial scales have been removed, the oleate of mercury, in the strength of ten per cent., may be used twice daily. This is to be kept up for at least three weeks; at the end of that time we may expect marked improvement. The process of recovery is often slow, and we are frequently obliged to increase the strength of the local application to fifteen or twenty per cent.

---

REGULARS AND HOMŒOPATHS IN SAME HOSPITAL.—The County Hospital (the large public hospital) in Chicago is to be placed, in part, under the professional control of the homœopaths—at least it has been so voted by the County Commissioners, which is the governing body of the institution. Only a part of the hospital is to be turned over to the homœopathic profession, the remaining portion, it being intended, shall remain under the present medical management.

The arguments that were considered by the Commissioners in taking this step were, that a large portion of the taxes were paid by patrons of homœopathy who desired to have that school represented in the hospital management, and that there was reason to hope that under homœopathic management the expenses of the medical department would be reduced. One of the two rival colleges of homœopathy has recently built a college building directly opposite the hospital.

THE NAUSEA AND VOMITING OF PHTHISIS are often relieved, according to M. Debove, by feeding the patient through a stomach-tube. This method was adopted on the theory that the sight and taste of food disgusted the patient. Seven successful cases are reported where nutrition was improved and all the symptoms were ameliorated. Yet we doubt if the remedy becomes popular.

# Progress of Medical Science.

A New Method of Embalming Bodies and Preserving Tissues. — Dr. Virodtzeff (*Balsamirovanie*, pp. xi., 164, St. Petersburg, 1881) recommends the following preparation as an efficient agent in the embalming of bodies and the preservation of tissues:

| | |
|---|---|
| Thymol | 5 parts. |
| Alcohol | 45 " |
| Glycerine | 2,160 " |
| Water | 1,080 " |

It is cheap, innocuous, free from unpleasant odor, possesses the property of keeping the body soft, elastic, fresh, and life-like, and does not ruin instruments. Thymol is selected as being superior to other antiseptics, and glycerine is added, both on account of its own preservative qualities and to retard the evaporation of the fluid. For the preparation of tissues the same solution is employed. If the cadaver be quite lean, or the tissues very delicate, equal parts of water and glycerine (1,620 of each) are combined with the above quantities of thymol and alcohol. To inject a body, half its weight of the fluid is necessary. A properly embalmed cadaver may be preserved indefinitely under ordinary circumstances, gradually shrinking and mummifying without putrefaction. Specimens are either to be injected with or macerated in this fluid. Maceration must not be too prolonged—the appearance of the specimen should act as a guide. The part, after having been thoroughly cleansed in water, and prepared, may then be exposed for months to the air without losing its consistency, form, and color. Permanent specimens may be enclosed in a hermetically sealed glass vessel containing a little of the same solution. Dr. Peabody has used this preserving fluid, with excellent results, in the New York Hospital Museum.

Some of the Therapeutical Uses of Nitro-Glycerine.—A paper, bearing the above title, was read by Dr. Hammond before the New York Neurological Society, October 4, 1881. "From the action of nitro-glycerine," says the author, "it is to be expected that the drug would be of value in those instances in which it was desirable to stimulate the circulation, and increase the amount of intracranial blood." As the basis of his prescriptions, he employs Boericke & Tafel's preparation, which contains ten parts of nitro-glycerine to ninety of absolute alcohol. This he dilutes still further, by adding to it alcohol to the extent of ninety parts to ten of the drug. One drop of the solution obtained represents one one-hundredth of a drop of nitro-glycerine, with a dose larger than which he never begins the treatment of a case. In the anæmic variety of hemicrania, one drop of the remedy of the above strength is administered. In fifteen minutes, if no benefit has resulted, another drop is given. The author states that he has rarely been compelled to administer a third dose, as improvement generally began with the first, while a second almost invariably completed the cure of the paroxysm. In periodical migraine, the patient should begin to take the solution in doses of a drop, three to four times a day, two or three days before the paroxysm is due, and continue the remedy for an equal period afterward. When an attack, due to indiscretion in diet, emotional disturbance, physical exertion, etc., is threatening, a similar course should be pursued. The author believes there is every reason to think that, eventually, the habit may be permanently overcome by this means. In the treatment of old cases of epilepsy, in which bromides have been exhibited, with only partial effect, he always begins with nitro-glycerine, provided there be no organic cardiac lesions present. The bromides are retained for their permanent influence. In that form of epilepsy known as the *petit-mal*, in which bromides, as a rule, have but little curative action, nitro-glycerine is of particular efficacy. In these cases, one drop of the solution is given three times a day, and the dose is increased one drop every month, until at the end of a year the quantity administered will be twelve drops three times a day. The author's experience has not been extended enough to warrant him to make confident assertions in regard to the permanent curative influence of the nitro-glycerine in epilepsy, but the therapeutical promise is good, especially as regards those forms of the disease in which there is little or no convulsive movement. In the *status epilepticus*, a condition in which the paroxysms succeed one another so rapidly that there is no conscious interval, results have been obtained better even than those following administration of the nitrite of amyl. The headache of anæmic women and anæmic vertigo are also very amenable to treatment by nitro-glycerine. — *Virginia Medical Monthly*, October, 1881.

Indications for the Administration of Digitalis. —In the *Deutsche med. Zeitschrift*, No. 23, 1881, Prof. Leyden states his views in regard to the use of digitalis. He thinks the drug is of advantage in acute febrile diseases, in hæmoptysis and other hemorrhages, and of course in cardiac diseases. As an antipyretic, however, it is not a very safe agent, on account of the danger of sudden collapse. As regards its employment in heart disease, he thinks it difficult to lay down any generally applicable rules. Every case should be judged on its own individual merits. In mitral and aortic affections there is a special indication for its use when there is diminished arterial tension, with dyspnœa and scanty secretion of urine. He finds it best in such cases to give only small doses, one-quarter or one-fifth of a grain daily. If these doses fail, it remains an open question whether or not it be advisable to give more. In hypertrophy and dilatation of the left ventricle, with co-existing pulmonary disturbance, digitalis is a highly uncertain remedy. As a diuretic its action is feeble, succeeding only when the action of the left ventricle is feeble. Leyden prefers the tincture and infusion of digitalis to other preparations of the drug. The best substitute for digitalis he thinks is squills. Both drugs may be given in combination, or, better still, the exhibition of digitalis may be followed by that of squills.

Gastrostomy.—Establishment of a Gastric Fistula in a Case of Stricture of the Œsophagus.— "Given a case of malignant stricture of the œsophagus below the neck," says Dr. Lutz (*Transactions of the Medical Association of the State of Missouri*, 1881), "what course are we to pursue?" After referring to the danger attendant upon the use of bougies, and the inefficacy of rectal alimentation, he considers the results of operations for establishing a gastric fistula. These results, he says, discouraging as they may appear, are, when properly analyzed, really encouraging, for they point out the causes of failure, and how to avoid

them. Magendie demonstrated that animals who have been starved, or ill-fed, cannot, after a certain time, be kept alive, even though their former allowance of food is again given to them, and, furthermore, they will die just as soon as if they had continued to be insufficiently fed, or starved. Here is a clue to the lack of success in the operations mentioned. With few exceptions, the patients had been allowed to become irreparably emaciated, or they themselves had deferred the operation until the power of digestion and absorption was lost. To show how much could be accomplished by an early operation in the way of rendering the patient comfortable, and limiting the influence of the new growth upon the general system, the author cited a case upon which he had operated six months before. The diagnosis was incipient, and probably malignant, stricture of the œsophagus in the lower third. A gastric fistula was established, the man was provided with an obturator and an *external œsophagus* of rubber, and at the time of the reading of the paper (May 17th) was "alive, well-nourished, and as comfortable as could be expected." On June 15th, however, seven months after the operation, the patient's health began to depreciate, the fistula gave him considerable trouble, introduction of the obturator caused him great pain, and he therefore took food but once a day; he died of exhaustion on the 2d of July. No post-mortem was made, the relatives refusing permission.

Leucocythæmia and Hodgkin's Disease.—Dr. Graham, of Toronto, has summarized the leading points of similarity and difference in these two allied diseases. He states: 1st. That the essential features of leucocythæmia are the lymphoid growths, and the leucocytes found in the blood derived from them. 2. That the existence of similar growths is the essential feature of Hodgkin's disease; but in it the leucocytes, for an unexplained reason, do not enter the circulation. 3d. That in both diseases the presence of these deposits or growths interferes with the manufacture of the red corpuscles, anæmia resulting. 4th. That these growths bear a strong resemblance to those of a malignant character, especially the sarcomata. And, lastly, that pernicious anæmia may arise as a consequence of leucocythæmia, or Hodgkin's disease, in the same way that it sometimes results from pregnancy or any other condition that interferes with the proper elaboration of the blood.—*Can. Jour. Med. Science*, November, 1881.

Nature of the Diphtheritic Contagium.—In the spring of 1880, Drs. H. C. Wood and H. F. Formad, under the auspices of the National Board of Health, began a series of experiments upon rabbits with a view of determining the nature of the contagium of diphtheria. The animals were inoculated with diphtheritic membrane taken from the throats of human patients. In the course of these researches, it was determined that there is nothing specific in the production of false membrane in the trachea, and that traumatic pseudo-membrane accurately resembles the diphtheritic, except that micrococci are not quite so abundant in it. The experimenters conclude that the disease produced by the diphtheritic inoculation was really rabbit-diphtheria, because the poison giving rise to it, the symptoms during life, and the post-mortem lesions were identical. In addition to this, the contagiousness of the disease was retained. They accept the experiments of Curtis and Satterthwaite, showing that the infectious character of diphtheria depends upon the solid particles of the membrane; furthermore, their researches lead them to conclude that the micrococci are in close relation with the essential poison of diphtheria, being either the virus itself or the producers of it. The results of culture of these bacteria lead them also to assert that there is no difference between the micrococci of simple sore throat and those of diphtheria, except in activity of reproduction; the two are the same organism, existing under different conditions. Drs. Wood and Formad believe that the vitality under artificial culture is in direct proportion to the malignancy of the case from which the plant is taken. They have succeeded in producing diphtheria by the inoculation of cultured micrococci, but never with those of a generation later than the second. M. Pasteur has indicated that an inert organism may become virulent, and *vice versa*, and in the same way they believe themselves able to prove that the micrococci of the mouth are really identical in species with those of diphtheria. That oxygen may be potent in converting a virulent into a non-virulent organism, they regard as probable, from the effects of exposure of dry membrane. The micrococci of a catarrhal angina or trachitis may, under favorable circumstances, be transformed into micrococci of diphtheria, and a self-generated diphtheria (*i.e.*, endemic) ensue, or external conditions may favor the transformation of inactive into active organisms, and these may lodge in the trachea and also cause diphtheria (*i.e.*, epidemic). In the first instance, the disease may spread by organisms exhaled by the breath. Diphtheria will vary in contagiousness according to the development of the virus—malignant diphtheria will be more contagious than the mild endemic form. The conditions outside of the body which favor the transformation of inactive into active micrococci, and agents destroying these organisms, remain yet to be studied.—*Phila. Med. Times*, October 22, 1881.

On the Nature of Operations in which the Membrana Tympani is Incised.—Dr. Roosa (*Arch. of Otol.*, September, 1881) states that he has abandoned all operations in cases of chronic proliferous (or non-suppurative) inflammation where there probably are adhesions between the ossicles, or between an ossicle and the promontory, together with an absence of mucus or pus in the tympanic cavity. Division of the membrana tympani, insertion of an eyelet, attempts at maintaining a permanent opening by means of incisions, and repeated paracenteses, have convinced the author that these procedures fail to relieve tinnitus aurium, to improve hearing, or to retard the advance of the incurable disease. In cases of accumulation of pus or mucus in the tympanic cavity, especially where the trouble is acute or subacute, paracentesis, *carefully performed*, is a valuable adjunct to other means of cure. The author would not advise it in every instance, as many cases are benefited by means of Politzer's method of inflation, and by proper attention to the throat and nostrils. Redness and bulging of the drum-head may often be remedied by the use of leeches, or by scarification of the membrane (Blake). In incising, Dr. Roosa favors the gentle method. He uses a small needle, and makes an incision just large enough to give exit to pus, blood, or mucus. Incision is often practised too early, and delay might have rendered it unnecessary. It is often too free, and sometimes so deep as to injure the walls of the cavity.

MANAGEMENT OF TEDIOUS LABOR.—In the *Edinburgh Medical Journal* of November, 1881, Dr. S. Hamilton makes some suggestions, which his experience has warranted, in the delivery of breech presentations. The use of the forceps in seizing the buttocks is important. An instrument measuring two and three-fourths inches from blade to blade, and one inch at the tips, failed to give firm hold, and he, therefore, uses a pair of Ziegler's, which have been brought together one-eighth of an inch closer in both directions. Although one finger, or two, hooked in the groin is the safest and most convenient instrument, yet when the nates are high in the pelvis, the traction exerted is not great, and in strong primiparæ requires long and exhausting application. As a safer instrument than the bare hook, the author recommends the handle of the common craniotomy crotchet, over which an india-rubber tube is slipped. A soft surface is thus afforded, and the utility of the crotchet is not interfered with. Dr. Hamilton rejects the use of the bandage, or thick tape, usually recommended in these cases, inasmuch as it is liable to do harm to the parts of the child, and, furthermore, is passed with difficulty when the nates are high in the pelvis. He resorts to an india-rubber tube to *give soft kindliness* to the band and facilitate introduction. A piece of crinoline iron is accordingly given the proper curve; it is then inserted in a small rubber-tube, eighteen inches long, and passed around the groin. Traction can then be employed without fear of doing injury.

PUERPERAL TEMPERATURES.—Dr. A. D. Leith Napier has tabulated some important deductions, as the result of extended observations. They are as follows: Temperature varies in the normal puerperal condition. In certain individuals it may be as low as 97° F., or as high as 99.5° for a week or more, without a bad symptom. The average for the three or four days immediately succeeding parturition is 98.5° to 99°; the subsequent heat is modified by the hour of delivery, but only to a small extent. The healthy puerperal range is 2.5°. No temperature over 99° (unless accounted for by individual nervous susceptibility) is normal after four days. The healthy patient may have an *occasional* night-temperature of 100° or 101° within the first four or five days, but a continuing, or even a morning- or day-record like this requires an explanation. Slight causes, *e.g.*, constipation, retention of urine, etc., give a rise to 99°–100.5°, sometimes more. Retention of clots, or secundines, 99°–101°, or upward; 103° at times. Cases of mastitis are mildly febrile for several days. Metritis (endo- and peri-) gives record of 103.5°, with slow pulse. Peritonitis has a single rigor, and a sudden early temperature of 104° or upward; the pulse is wiry. General peritonitis, if severe, 105.5°–106°. Pelvic cellulitis, oöphoritis, parametritis, etc., have a heat of 101°–102.5°; the pulse is weak and irritable; recurrent rigors mark fresh deposits of pus, and are followed by temporary increased heat, 104.5°. Pyæmia and uterine phlebitis average 103°, perhaps more. Cases in which the veins are affected rapidly reach 104.5°–106°, and end speedily. Pyæmia is frequently late in development—7 to 10 days. Septicæmia varies from 102.5°–107°; the heat is never less, at least for some period of the twenty-hour hours, than 102.5° if the case is properly established; the temperature is liable to variations, but after the normal has been reached, is less so than pyæmia; there is no security from remission until the night-temperature is under 100°; recovery may take place after 106°, but is rare. Mental emotion may show 104°, and even 106°, and we may sometimes have, in addition, symptoms resembling metro-peritonitis; these cases do not persist, and are generally normal in less than forty-eight hours. If the temperature does not rise within ten days from delivery, there is little risk of grave disease, unless from gross imprudence, in exposure to cold, or zymotic infection. Although the temperature is moderately low, 100°–101°, so long as the pulse continues 120, or more, we are not safe from relapse. No anxiety need be felt so long as the temperature is kept under 102°. However fast the pulse, if the temperature continues low, the prognosis is favorable. An evident exception pertains when the temperature is low from collapse. If the temperature is persistent at 102°, or frequently recurs to this point, there must be an abnormal organic condition. Temperature should be observed night and morning for the first seven days, and daily for three to seven days after, more especially if any instrumentation has been required for delivery, or if zymotic or epidemic disease prevails. When an abnormal temperature is discovered, it should be reduced to the normal as early as possible, by one or other agent. It is of the highest moment to bring it down to 100°, and *keep it there*, or lower. "A few exceptional cases of abnormal puerperal febrile conditions," says the author, "cannot be brought under this thermometrical summary; they require individual consideration."—*Edinburgh Medical Journal*, November, 1881.

OSSEOUS LESIONS IN HEMIPLEGIA.—M. Debove has made a few observations, before the Société Médicale des Hôpitaux, on the osseous lesions met with in hemiplegic subjects. As surgeon of the Bicêtre Hospital, he had observed several fractures in paralytic subjects, and he noticed, at the same time, that the fracture was always on the side of the hemiplegia. There was reason to believe that the bones on the affected side had undergone some alteration which rendered them more friable. At the autopsy of a hemiplegic who had fractured the humerus, M. Debove was able to observe that not only had the fractured bone undergone this change, but all the bones of that side were affected. In comparing the two sides, he found that the humerus of the paralyzed side was lighter than that of the other, the medullary canal was larger, and the substance of the shaft less compact. The Haversian canals were much dilated, and the bone was porous. There was evidence of fatty degeneration. These lesions were sufficient to explain the relative frequence of fractures in hemiplegics. M. Debove observed, however, that these fractures united very rapidly.—*Medical Press and Circular*, November 9, 1881.

LINIMENT IN PROLAPSE OF THE UTERUS.—In prolapse of the uterus, M. Cheron, of the St. Lazare Hospital, besides the application of a pessary to keep the organs in position, prescribes the following liniment, in order to ease the neuralgic pain from which many patients suffer: chloroform, ʒ iij., ether, ʒ iv., camphorated spirits, ʒ iij. These frictions on the lumbo-sacral region are attended with the best results. Also, to restore the tone to relaxed ligaments, he gives: bromide of potassium, ʒ iss., tincture of iodine, gtt. xv., tincture of aconite, gtt. xxiv., syrup of tolu, ʒ x. A teaspoonful before each meal.—*Medical Press and Circular*, November 9, 1881.

# THE MEDICAL RECORD:

## A Weekly Journal of Medicine and Surgery.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, December 31, 1881.

## BEDSIDE INSTRUCTION.

This city, with other medical centres in this country, has reason to boast of many facilities for clinical instruction. In fact, it is well conceded that none but populous places, with public institutions for the care of the sick, can afford the requisite amount of material for the purpose. The teachers of medicine, with a laudable desire to meet the demands of the rising generation of medical men, have neglected no opportunities for instruction at the bedside and in the operating theatre. Comparing the present facilities for clinical demonstration with such as existed even a quarter of a century ago, we count substantial progress; and this, too, taking into account the enormous and disproportionate increase of students of medicine. But we make no startling statement when we assert that clinical instruction in this and other large cities falls far short of what is needed by the large number at present engaged in the study of medicine. To meet the necessities of the situation as much as possible, clinics are given at the various hospitals and in the college amphitheatres. For various reasons the college clinics are most patronized by the ordinary student. With the exception of Bellevue, the other large hospitals are at inconvenient distances from the colleges, the expenditure of much time is required in travelling from place to place, and the visits of the attending physicians and surgeons are not always so arranged as to be made during the off-hours of the student. Hence, he is too often tempted to take notes of a clinical lecture, and view the patient through an opera-glass. With the best of intentions on the part of his teacher, he rarely has more than half a dozen times during the session an opportunity of listening to a heart, feeling a patient's pulse, or verifying existing respiratory phenomena. This is no more his fault than it is that of his teacher. The student must take his turn and the instructor gives him every advantage, in a general way, of the clinical material at hand. But, that this is entirely inadequate to the needs of the student, goes without the saying. In some of the hospitals, students in any number are forbidden to tramp around the wards and otherwise annoy the patients. Much less is it permitted that any but a favored few, mostly such as belong to private classes, may take any part in the examination of patients. Of course we speak of such sick ones as would not be materially harmed by such examinations. Hence, the actual seeing of patients in the wards of the hospitals and at the bedside is denied to the larger number of students; and it has been proven in one of our sister cities that a student may graduate from a first-class medical college, and yet never, clinically speaking, see a case. But aside from the manner of clinical teaching, the material ordinarily presented at the college clinic is not such as will be generally useful to the student. Excepting the cases of Bright's kidney, chronic rheumatism, and phthisis, which are always at hand, the diseases such as he will see in his future every-day rounds as a general practitioner are sadly wanting.

Although it is the intention to give at least one obstetric case to a student before his graduation, the impossibility of carrying out such an intention would, considering the number of students to be supplied, involve a ten-fold increase of the present birth-rate, even among the otherwise prolific poor. Hence it is that many a young practitioner seldom has an opportunity of groping for the patulous os at the bedside of his first parturient, of making out the presentation until the head is in the perineum, and of liberating a supposed retained placenta until the latter is in the vagina. How often has the ordinary student a chance for seeing a simple case of measles, scarlet fever, or colic, until he is brought face to face with the puzzling realities in his own practice? Although the same may be said, in a less degree, of the utility of the surgical cases presented at the clinics, there is hardly one student in ten who ever feels bony crepitus until he has a case of his own, or has the opportunity of passing a catheter before being called to his first case of retention. It must be admitted that many of the difficulties in clinical teaching are almost insurmountable, and this must necessarily be the case so long as it is conceded that it is not the chief end of a patient to be the subject of clinical study. How to overcome some of these obstacles is the question with many clinical teachers. The "walking cases" which present themselves at the clinics are by no means as useful and desirable as they might be, while the more acute and interesting cases in the hospital-ward, such as are seen in every-day practice, are not visited as they should be. In view of the latter fact, we almost deplore the passing away of the old-time preceptor, who would have his pupil

accompany him in his rounds, demonstrate to him the progress of the ordinary diseases, and exemplify all the necessary details of treatment.

To make the most of the facilities at hand, it would seem necessary that some more practical and efficient system of hospital visitation than that now in vogue be instituted for the advanced students.

While not entirely supplying the demand for more practical clinical instruction, very much might be done in the direction of developing the same. A large amount of hospital material, so far as the good of students is concerned, is running to waste, and can, by a properly systematized arrangement, be made available to them. It does not appear impracticable to form small classes among the senior students in the colleges, and distribute the same among the different hospitals for stated periods. Nor would it be impossible to train such students as hospital-dressers, after the English plan, or as assistants to the house staff, as in some of the Continental hospitals. At all events, an improvement on the present plan of clinical teaching becomes more and more imperative as the number of students increase and the demands of a great medical centre become more and more apparent. As it is, the real clinical advantages of our hospitals are confined to the few who, after much competition, obtain positions as residents and walkers, while the larger majority of graduates go into practice with little or no previous clinical experience. All cannot expect to gain admittance as internes, but the larger majority of earnest students should not be denied the privileges of bedside instruction in our hospital wards.

---

THE EXPERT TESTIMONY FOR THE PROSECUTION.

ELEVEN medical experts have, up to the time of our writing, testified to the sanity of Guiteau, and are thereby courteously relegated by the defence to the category of "liars or ignorami."

Dr. Fordyce Barker, who was first summoned, was asked, among other things, "whether a man's assertion that he was a chosen instrument of God, and was in direct communication with him as his trusted agent, would be evidence of an insane delusion." His reply embodied a point which we have already insisted upon, viz., that the previous character of the man, his habits, and general moral status must be considered in deciding upon a given act or opinion. Dr. Barker said: "Where such an assertion is put forward as a symptom of insanity, it is susceptible of proof. If the act were inconsistent and contrary to the previous habits and normal character of the individual, it would be a strong presumptive evidence of insanity. For example, if a man who has always been a hard-working, industrious man, of correct habits, moral, affectionate, fond of his wife and children, should cut the throat of his child and give as his reason that he was directed by the voice of God, that would be almost a sure proof of insanity; whereas, where a man had been always a tyrant to his wife and children, utterly reckless in his conduct of bad impulses, regardless of the laws of God and man, such an excuse would not be a defence, and would not be any evidence of delusion."

Dr. Barker denied the existence of moral insanity, saying that such a thing is unknown to science. This statement is a very extraordinary one. From other testimony given, however, it seems that the witness meant that there is no disease of the brain affecting the moral sense alone and conspicuously. Insane people were thought by the witness to be responsible for as much wickedness as they could restrain themselves from doing.

Dr. Webster Noble, physician to the District prison, testified to the sanity of the assassin. Dr. Noble had had frequent opportunities of seeing Guiteau, and had never observed anything abnormal in his mental characteristics while in jail. The witness also testified that Guiteau did not seem to feel any great confidence in his inspiration at first, and laid much less stress upon it. A lay witness who saw Guiteau twice shortly after the assassination gave some very strong evidence to this same effect.

Dr. Francis D. Loring, of Washington, testified simply to the fact that his pupils responded normally to light, that the retina was normal, and that the eye in general showed nothing which indicated cerebral disturbance.

Dr. Allan McLane Hamilton, of this city, testified that there was nothing in the physicial appearance of the prisoner from which anything of positiveness or value regarding the mental condition of the prisoner could be drawn. Dr. Hamilton said that the head presented no abnormality, except a slight bulging on one side. The witness considered Guiteau to belong to the class of the insane neurotic, or eccentric. He also thought that persons who were judged "medically insane" might still be responsible. Dr. Hamilton was subjected to a long and close cross-examination, which elicited nothing, however, favorable to the defence.

Dr. Theodore Damon, Superintendent of the Asylum for Insane Convicts at Auburn, New York, was an important witness for the prosecution, both on account of his ability and his experience with a peculiar class of the insane. This witness stated that he saw nothing in the prisoner which was not the result of his natural character, early training, and the life he had led.

Drs. Samuel Worcester, of Boston, and H. S. Talcott, of the Homœopathic Asylum, at Middletown, New York, had both been summoned by the defence, and had gone to Washington with a belief that Guiteau was insane.

The same was true of Dr. Henry P. Stearns, of the Hartford Retreat, at Hartford, Connecticut. These

gentlemen had all changed their views upon a closer examination of the prisoner. Dr. Stearns insisted, as one of his reasons for believing in Guiteau's sanity, that an insane delusion, culminating in an act so dreadful as that of the assassination, would probably have left a profound mental disturbance.

Dr. Orpheus Evarts, of the College Hill Sanitarium, Ohio, and Dr. Abraham M. Shew, of Middletown, Connecticut, testified that they had examined Guiteau and found no reason to believe him insane, either now or on the 2d of July.

Dr. A. E. MacDonald, of New York, testified very emphatically to the sanity of Guiteau. He also created some sensation by declaring his belief that Guiteau had been shamming to a great extent while in court.

---

### EXPERIMENTAL INVESTIGATIONS REGARDING THE PATHOLOGY OF MALARIA.

We recorded some time ago the experiments made by Klebs and Tommasi-Crudeli, in order to discover the nature of malaria. These gentlemen announced, as the result of their work, a belief that the infective poison of malaria lay in a small organism, which was named *bacillus malariæ*.

Under the direction of the National Board of Health, Dr. George M. Sternberg, U.S.A., has made some carefully conducted experiments, for the purpose of confirming, or otherwise, the results of the European investigators.

Dr. Sternberg went to New Orleans to carry on his studies. Being located there, he took samples of the surface-mud from two swamps, also mud from the river *batture*, and from certain squares in the city of New Orleans. This he placed in different tin vessels with perforated bottoms, the vessels themselves being placed in a shallow dish of water. In this way small "artificial swamps" were created, upon which organisms were allowed to develop. Some of the mud from these vessels, with its contained organisms, was added to various solutions of fish-gelatine, and the subsequent developments watched. In the "artificial swamp" mud Dr. Sternberg found diatoms, amœbæ, infusoriæ, etc., as well as minute algæ and bacteria. Some of the bacteria bore a strong resemblance to those described by Klebs and Crudeli as *bacillus malariæ*. Still, the identification was not a certain one. In the gelatine cultures the ordinary *b. termo* of putrefaction was almost always largely predominant.

Small amounts of the mud and of the gelatine cultures containing these different organisms were injected into rabbits.

The object was to see whether this would not produce a fever which could be identified by clinical symptoms, or post-mortem changes, as malarial in character. Klebs and Crudeli based their diagnosis of the fever produced by inoculation of the so-called *bacillus malariæ* on the fact that there were remissions in it, that the animal at first increased in weight (an alleged characteristic of malarial fever), by the symmetrical enlargement of the spleen, and the deposit of pigment in the spleen and marrow of the bones.

Sternberg's experiments showed that unquestionably the gelatine cultures and the surface mud, with their contained organisms, possessed pathogenetic qualities. In nearly every case where these substances were inoculated, the rabbits succumbed to a resulting fever. But the character of the fever seemed to be only septic, and no evidence was obtained that the rabbits suffered from anything else. The points on which the previous investigators based their diagnosis of malarial fever were insufficient, as our author thinks, because (*a*) the temperature curve in their rabbits showed no distinctively paroxysmal character; (*b*) because healthy rabbits sometimes show diurnal variations in temperature as great as those indicated on the charts of Klebs and his co-worker; (*c*) because the changes in the spleen, described as characteristic of malaria, are found in rabbits who have died of septicæmia; and (*d*) because the presence of pigment in the spleen cannot be taken as evidence of death from malarial fever, inasmuch as this is frequently found in the spleen of septicæmic rabbits.

The conclusions of Dr. Sternberg are, therefore, that the experiments of Klebs and Crudeli are not conclusive.

The fevers brought on by the inoculations of swamp-mud, or gelatine cultures, were probably septic, and not malarial.

Still, though there is as yet no experimental proof that malaria is caused directly or indirectly by microscopic organisms, Dr. Sternberg is very confident that some of these do contain the specific poison, and he makes a strong appeal for further experimental investigation.

It is suggested that crucial experiments can only be performed upon man himself. We think it quite certain that not much more can be learned by inoculating rabbits. There have been quite as many extravagances and errors made, as truths obtained, by experiments upon these scrofulous animals. Yet it may not be necessary, at first, to experiment upon man, in order to determine where the malarial poison has been obtained. At least, there are high authorities who state that sheep, and even horses and other domestic animals, are subject to undoubted attacks of ague.

One is impressed with the hard work required, in order to give any special *bacillus* an assured place as a cause of disease.

# Reviews and Notices of Books.

Ueber den Kreislauf des Blutes im Menschlichen Gehirn. Untersuchungen von A. Mosso. Mit 87 Abbildungen im Text und 9 Tafeln. Leipzig: Verlag von Veit & Co., 1881.

Researches on the Circulation of the Blood in the Human Brain. By A. Mosso. With 87 Illustrations on wood and 9 Plates. 8vo, pp. vi., 222. Leipsic, 1881.

This volume is written in German, although its author, Professor Mosso, of the University of Turin, is an Italian. It is dedicated to Moleschott, whose influence is markedly appreciable in the writings of his pupil. A historico-critical introduction summarizes in a very thorough way the labors of various writers upon this subject, from the Græco-Roman period down to the present day. Mosso was enabled to study the cerebral circulation principally upon three subjects who had sustained a loss of substance of the skull. His technical improvements in the apparatus necessary for continuous registering of the pulse, says the author, and his good fortune in obtaining a typical cranial defect, enabled him to pursue such an important series of graphical studies on cerebral circulation that in his book he has relied almost exclusively upon his own researches.

In the chapter on general characteristics of the pulse, he states that all general sphygmic phenomena, with the exception of rhythm and in part of pulse height, are independent of the heart—are local manifestations. His views on this subject are to be further elaborated in a future work. The author then goes on to consider the cerebral circulation as modified by psychical influences, by slumber, chloral sleep, the condition of the blood-vessels and heart, by respiration, and by amyl nitrite. He furthermore devotes several chapters to collateral matters, such as the nature of sleep, the circulation in the rabbit's ear, experimental criticism of Quincke's and Pfeiffer's, Funke and Latschenberger's, and Bowditch's researches upon the pulmonary circulation, anæmia and hyperæmia of the brain, and the movements of the cerebro-spinal fluid.

In his chapter on the nature of sleep, he agrees with Carpenter, Lotze, and Maudsley, that in sleep, as well as in waking, there are unconscious psychical processes. He also asserts that his sphygmic experiments justify the statement that in sleep there may be a period of such profound rest of the psychical centres that all such processes are absent. Mosso has demonstrated experimentally, in regard to the circulation in the normal head, what Lorry and Capie endeavored to establish upon theoretical grounds. He concludes that the amount of blood contained in the cranial cavity does not vary, but that its distribution in the capillary, venous, and arterial systems is altered. Every arterial pulsation displaces an equal quantity of blood from the veins, and imparts to the venous stream a pulsatory movement like that of the arterial current. This mechanism explains what results from the fact that the veins of the cranial cavity have no valves, and open into vessels with rigid walls. The absence of valves favors circulatory fluctuations, inasmuch as the space created by arterial contraction is immediately occupied by a regurgitation from the veins, which would be impossible were valves present. The rigidity of the larger venous channels is destined to prevent interference with the circulation resulting from continual changes in the volume of the encephalon, due to various circumstances.

In the chapter on the movement of the cerebro-spinal fluid he experimentally proves that the views generally accepted in regard to this subject are erroneous. If a moment's consideration, he says, had been given to the abundance of cerebral veins, to the extreme dilatability of the vessels, and to the insignificant changes of volume caused by respiration, the assertion would never have been made that a negative pressure could be produced in the brain, sufficient to lift up a column of liquid like that contained in the spinal subarachnoid space.

Altogether, this volume is a highly instructive and elaborate essay on a subject in which contending views of a mainly theoretical nature have wrought great confusion. Mosso certainly deserves all praise for his efforts to throw the light of a series of unimpeachable experiments on this intricate matter. And if he has not accomplished all, he has, at least, accomplished enough to entitle him to the thanks of the profession.

A Handbook of Vertebrate Dissection. By H. Newell Martin, D.Sc., M.D., M.A., and William A. Moale, M.D. Part I. How to Dissect a Chelonian. New York: Macmillan & Co. 1881.

This little work forms the first of a series intended for the help of students and teachers in biology and comparative anatomy. The Chelonian is chosen here for description, partly because it is so difficult to dissect, and partly because the great persistence of vitality in its various organs after general death has taken place makes the animal a very useful one for physiological experimentation.

The present monograph is clearly and concisely written. The publication of a series, of which this is the first, indicates a growing interest in the study of biology, of which it is gratifying to learn the existence.

Iconographie Photographique de La Salpêtrière (Service de M. Charcot). Par Bourneville et P. Regnard. Tome I. Hystéro-Épilepsie. Tome II. Épilepsie Partielle—Hystéro-Épilepsie. Paris: Publications du *Progrès Médicale*. V. Adrien Delahaye et Cie. 1876–77, 1877–78.

These volumes form a novel, but most interesting and valuable contribution to clinical medicine. They are composed chiefly of the records of cases, but are unique in the fact that each case is illustrated with several photographs, showing the patients in different stages of their attacks. To carry out the design of a work of this nature requires more than ordinary care, as well as special skill and appliances. One of the authors, M. Regnard, interne at La Salpêtrière, happens to be a photographer as well as a physician. With the aid of the hospital authorities, he was supplied with instruments, and, indeed, a regular photographer's saloon was fitted up in connection with M. Charcot's laboratory. In this way M. Regnard was able to have his apparatus always at hand. When any typical attack occurred, he at once photographed the patient in the various stages of the disease. By this means we have presented accurate representations of the various phases of hysteria, epilepsy, and hystero-epilepsy. The characteristic attitudes and expressions are given in a way which no pen or pencil could imitate.

There are, in the first volume, forty illustrations of cases of hystero-epilepsy. These photographs

are supplemented with carefully written histories, and with comments upon the nature of the disease.

The second volume contains thirty-nine photo-lithographs, besides a number of woodcuts, and a somewhat fuller text.

The photo-lithographs are admirably done, and being permanent, make the second volume more valuable even than the first.

# Reports of Societies.

## NEW YORK PATHOLOGICAL SOCIETY.

*Stated Meeting, November* 23, 1881.

DR. T. E. SATTERTHWAITE, PRESIDENT, IN THE CHAIR.

### PACHYMENINGITIS CHRONICA.

DR. GEORGE L. PEABODY presented three specimens illustrating this affection. They were accompanied with the following histories:

CASE I.—P. M——, forty-five years of age, born in Ireland; married; a shoemaker, and without previous history; was admitted to Chambers Street Hospital, October 7, 1881, at 10.35 A.M. On admission he was unconscious; surface dry; temperature 99.4° F. Left side of face, and left arm and leg paralyzed, both as to motion and sensation. Left pupil dilated, right contracted. Right arm rigid; breathing stertorous; urine negative.

*Treatment.*—Ice-bag applied to head. Right pupil subsequently became dilated, but neither was responsive to light. Paralysis became general. Pulse was 72, temperature 106°, just before death. Patient died on same day at 6.50 P.M.

*Autopsy,* sixteen hours after death.—Only the points of interest were given. The left ventricle was considerably hypertrophied and slightly dilated. The valves were normal; the kidneys were in condition of chronic diffuse nephritis. The dura mater, on its inner surface and right side, was covered by a thick, false membrane of fully formed connective tissue, whose vessels contained much blood-pigment and many blood-vessels. Numerous clots of recently coagulated blood were lying upon the ascending parietal and frontal convolutions of the right side, and about four ounces of fluid blood spread over the surface of the right hemisphere. The convolutions were compressed by this blood, and the convolutions of the left hemisphere were distinctly flattened by the pressure thus indirectly put upon them.

CASE II.—Unknown man, about thirty-five years of age, was found on evening of November 13, 1881, in the street, in condition of unconsciousness. He was admitted to Chambers Street Hospital, November 14th, 5.30 A.M., still unconscious. He was reeking with the fumes of alcohol. Pulse intermittent and feeble; temperature, 101.5°; respiration shallow; pulils dilated; urine contains a small amount of albumen.

*Treatment.*—Hot-air bath and stimulants. At 9 A.M. pulse had disappeared at wrist, and the patient was sinking. Temperature, 98° F.; pupils contracted. Died at 10.50 A.M.

*Autopsy,* immediately after death. Body well nourished; no œdema; lungs normal; heart normal; kidneys in the condition of chronic diffuse nephritis, not far advanced; stomach and liver normal. On the left side of the falx cerebri is a layer of false membrane, made of fully formed connective tissue, containing blood-pigment, and markedly congested. It is about half an inch in width, and extends from a point half an inch behind the origin of the falx to the union of the falx with the tentorium cerebelli. On cutting through the dura mater a large amount of fluid blood escaped, probably eight ounces.

CASE III.—Mrs. G. R——, aged forty-seven; born in France; widow; nurse; was admitted to New York Hospital, May 15, 1881. Brought in an ambulance at 4 P.M. Patient was unable to give any history, and the facts were obtained from her friends. During the past week she has been much in the sun, and was well up to last night; then, on her return home, complained of headache and drowsiness. She went to bed, and was found this morning with paralysis of the right side of the body, and speechless.

On admission, pulse, 96, respiration, 18, temperature, 99.6°; well nourished; marked œdema of left hand; pulse full and forcible; patient very stupid—does not reply to questions, and does not appear to understand them; pupils dilated, and very sluggish; complete paralysis of motion and sensation on right side of body and face; reflex diminished in right leg, absent in right arm; no abnormal heart-sounds. Urine acid, sp. gr. 1034, contains urates. She remained in this condition for four days, pulse, respiration, and temperature being normal. She passed urine and fæces in bed. She then regained very slight motion in the right arm and leg. Then she became decidedly worse. Paralysis again became complete. Six days after the attack began she became comatose, with stertorous breathing. Her temperature rose to 103°. She continued profoundly comatose, and died on the ninth day, with a temperature of 106.2° F.

*Autopsy,* eleven hours after death.—Body well nourished; rigor mortis well marked; slight œdema of both lower extremities and of the left hand.

The kidneys were small; many cysts in the cortex; marked atrophy of the cortex; markings indistinct. There was about six ounces of fluid blood, which was very brownish in color (owing to abundant amount of blood-pigment dissolved in serum), beneath the dura mater of the left hemisphere. This, by its pressure, had very markedly disturbed the surface of that hemisphere. The dura mater in this situation was covered, as was seen, by a false membrane, which was of a brownish color, owing to the blood-pigment which it contained. This had been raised from the surface of the dura mater by extravasated blood. It was made of connective tissue, and seemed to be quite vascular. On the other side of the head there were smaller patches of false membrane on the dura mater, which contained, at the autopsy, mostly extravasated blood.

The walls of the left lateral ventricle were approximated by pressure. The brain-tissue was nowhere lacerated.

The only other lesion of interest was that of chronic diffuse nephritis, already alluded to, which was verified by microscopic examination.

### CEREBRO-SPINAL MENINGITIS, ACUTE ENDOCARDITIS, AND PERICARDITIS.

DR. H. N. HEINEMAN presented specimens removed from the body of a boy, fourteen years of age, with the following history: Z. T——, a clerk, Austrian, was admitted to the Mt. Sinai Hospital, November 19, 1881. Two days previously he was seized with severe headache, pain in the back and limbs, with a not very marked chill, followed by fever, with loss of appetite, constant vomiting, and epigastric dis-

tress. His bowels were constipated. Upon admission he was rational; complained of severe headache, epigastric and abdominal pain, and more or less constant vomiting; the tongue was thickly coated; the bowels constipated; pulse, 120, and feeble; temperature (rectal), 105.2° F.; heart and lungs negative.

November 20th.—Stomach was less irritable; patient rational, but somewhat apathetic; pulse, 130; temperature (rectal), A.M., 103.4° F.; P.M., 105.6° F.; no pericardial friction-sound; fæces and urine passed involuntarily.

November 21st, 6 A.M.—A purpuric eruption appeared first upon the chest, then on the face, and then on all the extremities, but little upon the back. Temperature, 104.8° F.; pulse, 140, feeble. At noon the patient was quiet; answered questions, though delirious; had photophobia, and the pupils were dilated and responsive; there was hyperæsthesia along the spine (no opisthotonos); dysæsthesia of feet and legs, most marked on the left side; the purpuric eruption was fading upon the chest; there were pin-point ecchymotic spots upon the body and extremities; a large ecchymosis upon the palmar surface of the left hand, and one over the left external malleolus. At 3 P.M. there was feeble and diffused apex-beat, and slight increased area of pericardial dulness; pericarditis was suspected by Dr. Weiss, acting house physician. At 11 P.M. a second crop of purpuric spots had appeared all over the body, also ecchymoses involving the entire fingers of both hands; the patient was pulseless; temperature, 106.2°; there were convulsive movements of the muscles of the face and body, most marked on the left extremities.

November 22d, 2 A.M.—Pulse restored, 160. At 3 A.M. he had a second slight convulsive seizure, and died at 3.20 A.M.

The autopsy revealed the following lesions:

*Brain.*—The pia mater was lustreless, congested, and inflamed; contained a few small, ecchymotic spots, and, in a few places, a very limited fibrino-purulent exudation. The posterior horn of the right lateral ventricle contained a tolerably firm, rounded clot, which had caused breaking down of the tissue of the occipital lobe and almost approached the surface. Deep in the substance of the left occipital lobe was a small, recent, firm clot about half an inch in diameter. The ependyma of the lateral ventricles was thickened. The pia mater of the cord was congested, inflamed, and somewhat opaque, but contained no exudation.

*Lungs.*—The bronchial mucous membrane was inflamed, coated by a thin, whitish layer of fibrin, and an abundant muco-purulent exudation. The lower lobes of the lungs were congested, the upper lobes were dry.

*Heart.*—The mitral valves were covered by recent vegetations. Near the apex in the anterior wall of the left ventricle was a small cavity indicative of a probable abscess and destruction of tissue. A zone of dark-colored heart-muscle surrounded it. The pericardial sac contained considerable purulent serum, and both pericardial layers were thickly coated by recent fibrino-purulent exudation.

*Liver and spleen* congested.

*Kidneys.*—Normal size; capsule not adherent. The left kidney contained numerous small yellowish and whitish abscesses about the size of a pin's head, each surrounded by a red zone. In the right kidney there was a large white infarction and a few small abscesses similar to those found in the left kidney.

The case was one of epidemic cerebro-spinal meningitis, with acute endocarditis and pericarditis. The infection had also involved the kidneys; and probably the exudation upon the mitral valve, as well as the punctate abscesses in the kidney, contained micrococci.

### WELL-MARKED SYMPTOMS OF CHRONIC DISEASE OF THE BRAIN, WITH ONLY CONGESTION OF THE VESSELS OF THE PIA MATER AND THE CEREBRUM AT POST-MORTEM.

Dr. Van Gieson presented a brain, accompanied with the following history: It was removed from the body of a man thirty-six years of age; well-developed, strong and muscular, and of good constitution. He had had exceptionably good health, was married, and temperate in his habits. He had never had syphilis. His parents are still living, and in good health. Up to last January [1881] he had had no feeling of illness; attended to his business regularly; but was occasionally taken with a severe pain in the left side of his head.

Some weeks before this he fell from a wagon, struck upon his head, received a scalp wound, picked himself up and drove on, not attaching enough importance to it to think it necessary to consult a physician. His wife, in the absence of any other apparent cause, ascribed all his subsequent trouble to this fall, although the interval between it and the development of the pain in the head was some weeks. From January until February 15, 1881, he had a fever and was confined to his bed for four or five days, during which time he had several tonic convulsions. He left the bed in five days and applied himself to business. In about a week he had a similar attack, lasting four days, again attended with tonic spasms.

His physician told his family that he was suffering from cerebral hyperæmia from over work, and advised complete rest from business. The advice was not followed. Not long after, a third and more severe attack set in, spasms being again a prominent feature of the illness. During this third attack he had also double and indistinct vision. He again recovered, and spent a few weeks in the country, and was not, during this time, under the care of a physician, but had one or two attacks of spasms again.

Dr. Van Gieson first saw him on May 24th, P.M. His temperature was then normal; pulse, 56, full, but compressible; he was entirely sensible, and gave the doctor the foregoing facts in the history of his case.

May 26th.—Has had several convulsions since last visit; has little or no pain in the head.

May 29th.—Pulse, 50; respiration normal; temperature normal; urine normal; heart and lungs normal.

Diminished power in grasping with right hand; has double vision; unable to read print at any distance with both eyes; with the right eye closed, he can see more distinctly with the left eye; there is loss of muscular power on the right side; but he is able to move the arm and leg freely; there is no loss of sensation, but rather general hyperæsthesia; a slight irritation, sudden pricking of the skin, will bring on a convulsive movement which is tonic in its character. The head is slowly thrown back, the eyes become fixed, the muscles of the arms and legs become rigid, and remain so for a few seconds, sometimes the greater part of a minute; then comes a sudden relaxation; this may end the attack, or he may have a repetition. There is no frothing at the mouth; no biting of the tongue; and, during a slight spasm, he does not entirely lose consciousness.

May 30th.—The bowels have not been moved in five days; pulse, 56; urine made but twice in twenty-four hours. One-third of a minim of croton oil, repeated every four hours, gave, after the second dose, a moderate passage. This was followed by 5 grain doses of kal. iod. every two hours, with 20-grain doses of ammonii bromide every two hours during the night, to control the spasms.

June 1st.—Slight improvement; increased kali iodide to 10 grains.

June 4th.—Pulse, 52. Right leg cooler than the left; has passed no water in thirty-six hours; has had no convulsions since 31st ult.

June 6th.—Can see clearer; has no double vision, and can read coarse print; pulse, 64; bowels constipated; intellect clear; only slight headache.

June 14th.—The treatment has been kept up. Condition about the same. Vision is clear, only double at times; pulse varies from 48 to 56; obstinate constipation is a prominent feature; gets a fair amount of sleep; is unable to stand alone; right leg weaker than the left; tendon reflex in both legs normal.

This A.M. his wife was accidentally shot by her brother-in-law, who was handling a small pistol in the sick-room. The wound, though not mortal, was a severe one. This accident threw him into violent and long-continued convulsions, requiring one or two strong assistants to hold him during their height.

June 25th.—He has returned to his usual condition. He is entirely rational, and very anxious to resume his business. He has an average of about three convulsions daily.

June 27th.—Consultation with Dr. E. G. Janeway. It is thought that cerebral humor exists. The prognosis is fatal. Elevation of temperature and coma may be expected to precede the fatal result. The duration of the disease is uncertain. Its progress will be slow.

July 10th.—Pulse, 48 to 56 during the interval. Obstinate constipation persists. Continue the treatment.

August 1st.—Condition unchanged; vision better; reads newspapers at times; intellect clear; memory defective.

August 25th.—Has been twelve days without a convulsion. Is very much emaciated, and daily growing weaker. Temperature has remained normal throughout. Pulse varies from 48 to 56.

September 14th.—No special change; the intensely hot weather has materially weakened him. The spasmodic movements occur at long intervals. The loss of muscular power on the right side is very marked. The vision has improved. Treatment suspended, except occasional doses of bromides and chloral hydrate.

October 8th.—Is inclined to stupor; is awakened with difficulty. Pulse, 60; temperature normal. Emaciation very marked.

October 18th.—Has been free from convulsions for two weeks; the bowels move, without medicine, every second day. His intellect is clear. The tendency to stupor has disappeared. He is wasting rapidly. There is retraction of the abdominal walls.

October 29th.—He is again inclined to stupor, quite profound.

November 1st.—He lies motionless, the eyes open and fixed; the pupils contract to light, but the eyes do not follow the light when moved from side to side. Respiration, 24, pulse, 68, temperature normal. When loudly spoken to he replies sensibly in a faint whisper. He is unable to swallow.

November 4th.—Remains in the same condition—has had two slight convulsions daily. Desires cold water continually poured on the head. When the affusions are stopped for a time, he faintly makes signs, and with indistinct whispers desires to have them renewed. Though unable to swallow, he requests ice-water to be poured in his mouth. If his requests are attended to he will remain motionless for hours, but if the pouring is long withheld he becomes impatient.

November 9th.—The affusions have been kept up with but slight remissions. Pulse, 120, faint and thread-like. The cornea dim. Mucus exudes from the corners of the eyes. He says occasionally, in a faint whisper, that he thinks he will get better. Slight convulsions have occurred two or three times daily, followed by distressing fits of coughing. He remained nearly in this condition, growing weaker each day, until November 16th, when he quietly died at 10 A.M., having swallowed not a drop of fluid for fourteen days.

The necroscopy was made at 1.30 P.M. the following day—about 27 hours after death, Dr. J. A. Jenkins, of Brooklyn, assisting. The cranial cavity and contents only were examined. The pia mater was found intensely congested. About one and one-half ounce of serous fluid, faintly tinged with blood, was left in the cavity of the skull when the brain was entirely removed; no further examination of the brain was made at that time. The next day it was carefully examined by Prof. Janeway, with negative results. The main lesion, to the naked eye, was very marked congestion of the pia and the vessels in the substance of the brain. Small portions from various parts of the brain were placed in Müller's fluid for microscopic examination, but the examination thus far had given negative results.

### GRAINS OF GUNPOWDER EMBEDDED IN THE SKIN—REMOVAL WITHOUT REMAINING DISCOLORATION.

DR. B. A. WATSON presented a boy who, on the Fourth of July last, had a large number of grains of gunpowder lodged in the skin of the right side of his face—the cheek, nose, and lips. The operation for their removal was done in the following September, and consisted in taking away small discs (eighty-four in number) of the integument, including the grain of gunpowder. The deformity left was very trifling indeed. The instrument with which the operation was performed was called a discotome. [See MEDICAL RECORD, vol. xiv., p. 78.]

### PNEUMONIC PHTHISIS—EARLY FORMATION OF CAVITIES.

DR. BEVERLEY ROBINSON presented the lungs removed from the body of a man who died in St. Luke's Hospital, November 11, 1881. He was admitted to the hospital October 17th, when there was found evidence of general bronchitis, with consolidation in lower two-thirds of the right lung. Three weeks previous to admission he had a chill, cough, and hæmoptysis, and the spitting of blood (of a bright red color) had continued daily, more or less. He had slight night-sweats, loss of appetite, dyspnœa, but felt very well when he had no hemorrhage, and when admitted was well nourished and did not seem weak. Pulse accelerated and temperature elevated. In the latter part of October a noticeable feature was a difference of 5° F. between the morning and evening temperature.

At the autopsy, the right lung was found firmly adherent to the chest by recent adhesions. The middle and lower lobes contained cavities of varying

size, the largest being in the upper portion of the lower lobe, and of the size of a pigeon's egg. The left lung was œdematous and deeply congested, contained several points of extravasation, and spots of commencing cheesy pneumonia.

The spleen was small and firm. The kidneys were fatty; capsule neither adherent nor thickened. Weight: left, five and one-half, and right, four ounces.

The points of special interest were the rapid development of phthisis, and the notable fluctuations of temperature.

TYPHOID FEVER—SUDDEN DEATH—ANTE-MORTEM HEART-CLOT.

Dr. Robinson also presented the heart removed from the body of a man, thirty years of age, who died suddenly during the progress of typhoid fever, in St. Luke's Hospital, November 12, 1881. Death occurred on the nineteenth day of the disease. The patient's temperature had not been very much elevated until the second day before his death, when it reached 103½° F., and the pulse, 120. Diarrhœa. On November 9th and 10th he was delirious and weak; on the 11th, semi-comatose; and on the 12th, his breathing became very rapid without apparent cause; face and extremities not cyanosed, and he gradually sank, and died at 9.15 A.M.

At the autopsy, there were enlarged and softened spleen, splenization of the lungs, fatty kidneys, swollen solitary follicles, and numerous ulcers scattered along the entire length of the ileum. The ileo-cæcal valve was thickened and extensively ulcerated.

The feature of special interest was the existence of a long, slender, fibrinous clot attached to the aortic and mitral valves, and extending, ribbon-like, into the aorta. There was also an ante-mortem clot attached to the chordæ tendinæ. There was quite extensive granular degeneration of the muscular fibre of the heart.

According to his observations, there was a marked difference between the condition of the heart of a patient dying of typhoid fever and of one dying of diphtheria. Although apparently similar in character, he had found the right heart, ventricle, and auricle, in diphtheritic patients filled, as a rule, with a mass of fibrinous deposit, which seemed to have been formed some days prior to death. In several cases of death from typhoid fever he had found the blood in the right heart liquid, and in the left heart fibrinous masses of small dimensions, but they did not seem to be the immediate cause of death.

With reference to treatment, he asked to what extent alcoholic stimulants and heart-tonics, such as digitalis, nux vomica, etc., could be pushed with advantage in cases similar to the one reported.

Dr. J. Lewis Smith referred to the prevalence of a continued fever in the northwestern part of the city, and was inclined to attribute it to the insufficient supply of Croton water, which prevented proper washing of the waste-pipes in some of the tenement-houses. In some of the cases the disease had lasted three or four weeks, and had usually terminated favorably. Diarrhœa had been absent in some of the cases, and in none which he had seen had he been able to find the rose-colored eruption.

Dr. Wendt said that an irregular type of typhoid fever was prevailing in some of the lower and eastern districts in the city. He had made several autopsies, but had not found extensive lesions either in the intestines or other organs. He believed that a certain proportion of these patients would die irrespective of treatment.

Dr. Robinson believed there was not much correlation between a certain amount of rise of temperature and granular degeneration of tissue in diseases of the ordinary infectious type.

The President remarked that a reciprocal relation did not always exist between the two conditions, especially in the English cases, where the temperature rose to 114° and 120° F. and the patient recovered. The excessive temperature in those cases was doubtless due to some affection of the sympathetic nervous system rather than to organic disease.

Dr. J. Lewis Smith presented a specimen of

RACHITIS.

The society then went into executive session.

## MATERIA MEDICA SOCIETY.

*Stated Meeting, November* 26, 1881.

Dr. Piffard, President, in the Chair.

ACIDUM BORACICUM AND CALENDULA OFFICINALIS IN AURAL AFFECTIONS.

Dr. Sexton read a paper on the above topic, in which he gave the natural history of the drugs, their chemistry, and a thorough résumé of the literature of the subject. Old writers recommended calendula in a variety of morbid conditions, employing it in ulcers of the womb, uterine enlargements, cancer, as an emmenagogue, anti-emetic, diaphoretic, vulnerary, etc. He contrasted its extensive use in the past with the present neglect of the remedy. Boracic acid was an efficient anti-septic, exerting no toxic effects on the system. The two drugs in combination might be advantageously exhibited in aural affections, notably in chronic suppurative otitis media.

The discussion was opened by Dr. Farnham, who stated that he had never used the remedies in combination. Boracic acid he had used with satisfactory results in cases of eczema of the scrotum. He thought it was rather more irritant than Dr. Sexton was inclined to believe, and had employed it in one to five per cent. solutions. He had used calendula as a vulnerary on the recommendation of Dr. Piffard, and had found it of value both in ulcers and fresh wounds. It had given him satisfaction as a healing agent after the application of caustics.

Dr. Johnson stated his belief in the antiseptic effects of boracic acid, but expressed doubts as to the vulnerary virtues of calendula. It was difficult to prove that anything helps the healing of incised wounds in the healthy subject, as the reparative process was, in the large number of cases, accomplished when the wound was left alone. When the infusion of calendula was used, the effects might be due rather to the water than to the calendula. In ulcers it might have sufficient irritating properties, like those possessed by a thousand other remedies, to stimulate the ulcerating surfaces. He did not believe it had any specific effect in these cases. In regard to its use in cancer, ulcer of the womb, uterine enlargement, etc., he thought the statements of authors of the past were comparable to the opinions held by knowing old women as to the miraculous powers of various household remedies.

Dr. Bronson had used boracic acid in a few instances. He had employed it in two cases of bromidrosis with apparent success, directing the patients to soak their stockings at night in a saturated

solution of the drug. As, however, he had, in addition, used salicylic acid and other remedies, he could not say which had contributed most to the patients' improvement. The Germans were employing it in cutaneous affections. He had had no personal experience with calendula.

Dr. Webster had had some experience with boracic acid in chronic suppurative inflammation of the middle ear, and considered it a valuable remedy in that disease. After the ear had been syringed out with warm water and dried with absorbent cotton, the powdered acid was blown in by means of the powder-blower. He had met with cases that had resisted treatment by nitrate of silver, alum, and sulphate of zinc, which yielded to boracic acid. Again, other cases were not benefited by the acid. He did not know the differential indications of the various remedies mentioned, but was sure that in certain instances the acid was efficient in the treatment of ulceration and discharge. Some of the good results attributed to boracic acid might have been due to the enforcement of cleanliness, as this alone frequently sufficed to bring about a cure. He had no personal experience with calendula, but knew that it was used as a household remedy in the form of marigold tea for colds.

Dr. Castle has not had an extended experience with boracic acid, but had used it in catarrhal discharges from the cervix and body of the uterus. He had employed it in solution, never in powder. When used in this manner at daily intervals, it lessened the discharge and improved the character of the inflammation. As to calendula, he was not sure that it was of special service as a vulnerary, but could not recollect any cut or fresh wound which had done badly when dressed with it.

The President remarked that Dr. Sexton's paper was important, as giving in collected form such a résumé of the literature of the subject as could not elsewhere be found. It would be of advantage if the literature of all the older drugs, which have now fallen into disuse, might be thus compiled, although, as Dr. Johnson said, the isolated opinions of writers of the past might often be of no value, yet when, without copying one from another, the authors were unanimous in regard to a certain point, this point deserved attention. Such a coincidence of opinion existed in regard to the vulnerary virtues of calendula in wounds and ulcers. That it was supposed to be efficient in cancer was probably due to the fact that, in the past, simple ulcers with indurated margins were frequently diagnosticated as cancers. Rust, a careful observer, recommended it in cancerous ulcers. The President thought the remedy should be tried in this direction; if a mild drug could be used instead of the knife or caustic, the fact was worth knowing. He used it in his practice as a vulnerary in cuts inflicted by himself, and in other cases, and had seen it employed in his childhood as a domestic remedy. In the majority of instances, it would be impossible to prove that the drug had promoted healing, as this would have taken place anyway; but, in a number of cases, he was certain of its efficacy. When a wound is sewed up, he said, and the stitches are left in four or five days, suppuration is apt to follow the course of the suture, but in wounds dressed with calendula he has often observed that no suppuration took place. In a lesion of continuity of the forehead, he sewed up the wound with silk, and employed the calendula dressing; in the same patient an application of chloride of zinc (an antiseptic and antiputrefactive) was made elsewhere. The wound in the forehead, in spite of sutures and ligatures, healed without suppuration, although the patient was scrofulous and had lupus of the face; wherever the zinc had been applied, there was suppuration. Calendula had also prevented suppuration after an operation for cancer of the lip, although the ligatures were not removed until the tenth day. He recommended the remedy as a dressing for wounds. In ulcers, suppurating too freely, it was of as much service as carbolic acid, and was not objectionable on account of its odor. As alcohol in itself was an efficient dressing for wounds, he experimented with preparations containing no alcohol, and obtained good results.

Dr. Sexton had had but little experience with boracic acid. He had found the application of the powdered boracic acid to be of service in removing the odor in suppurative inflammation of the middle ear. He expressed himself, in general, extremely satisfied with the application of the remedy. A number of cases which had been greatly aggravated by nitrate of silver and other strong applications, which had been sent to him, yielded to boracic acid and calendula. Cleanliness was, of course, necessary, but he thought syringing and cleansing the ear was sometimes overdone, and harm produced; some cases would recover much faster without syringing. On account of the solubility of the remedy in water, there was no danger of its forming concretions in the ear. In cases of active suppuration it is retained with difficulty; the parts should, therefore, be dried before the application is made.

In Italy, it was remarked, boracic acid was used to preserve butter, and in the United States to preserve cider. In France, infusion of mugwort and marigold had a reputation as an emmenagogue. The diaphoretic and anti-emetic effects of calendula were not regarded as specific.

The society then went into executive session.

---

Pasteur's Vaccinations.—Statistics, brought up to October 1, show that the inoculations of splenic fever, according to Pasteur's method, were performed on 160 flocks, comprising 68,900 sheep, of which 33,576 were vaccinated, and 21,938 left uninoculated, so as to judge of the results of the difference of treatment. Before vaccination, the losses caused by splenic fever amounted, in the whole of the flocks, to 2,986 animals. During vaccination, and until its effects were perfected, 260 sheep out of the whole number of 33,576 perished. During the same period the mortality rose to 366 out of the group of 21,938 which were not vaccinated. When the effects of vaccination were complete in the first group, the mortality from splenic fever fell to 5. This rate has persisted up to the present time, and the next statistical account will give, it is expected, the same satisfactory results as regards the groups of animals vaccinated and left unvaccinated.—*British Medical Journal.*

Hot Water in the Treatment of Eye Diseases is highly recommended by Dr. Leartus Connor (*American Journal of Medical Sciences*). He believes it to be the sole agent which will induce contraction of the blood-vessels without irritating the eye. The water must be as hot as can be borne, and must be thrown against the eye with the hand. It should be used two or three minutes three times a day, or for five minutes every half hour, according to the indications.

# Correspondence.

## WATER TRANSPORTATION IN FLORIDA.

To the Editor of The Medical Record.

Sir: The time was when only those who could brave every discomfort went to Florida. They consisted of two or three small classes: the consumptive, in search of a genial winter atmosphere; the sportsman, to fish and hunt; and the dealer in lumber. At that period, the means of access by land, the hostelries, and the boats upon the rivers and lakes, were peculiarly bad. At the close of "the war," a new era at once began. A leading citizen of Jacksonville told me yesterday that when he moved into that town in 1857, one or two horses and carts did the business for the place, and that no one thought of selling oranges. A plot which to-day is worth one hundred thousand dollars then sold for one thousand. Last year a firm in the grocery trade did a business of one million of dollars, and during the winter season now, fifteen or twenty steamboats, and a great number of other vessels plying on the St. John, are taxed to their utmost capacity to carry the promiscuous freight to the interior, and bring away the millions of oranges and other products which are shipped to every part of the United States. Into the State is flowing a steady stream of tourists and settlers. Railways are built, projected, or in process of construction, opening up all parts of the State, and there is a universal spirit of thrift which betokens successful industry, satisfaction, and hope. I only mention these things as incidental; they have a sanitary bearing, it is true, of vast importance, inasmuch as the majority of those who go to the State in search of health must also find a means of livelihood. It is interesting to observe that the flow of settlers into the State is largely from those portions of the East, North, and West in which the winter is long and depressing. Very many come from Maine, Vermont, Massachusetts, Illinois, Wisconsin, and Minnesota. Such emigrants tell you that after some years of trial they have grown weary of the long winters, in which so many industries are compelled to hibernate, and that their health has begun to succumb under the prolonged cold. I have talked with such persons during my brief sojourn here, and learned that they are satisfied with their change, and do not find the summers oppressively hot or debilitating. The chief industries are agricultural. The increase in the acreage of orange groves is most remarkable. This is also true of vegetables for the northern market. All these occupations are said to be remunerative, and afford a variety of out-of-door employments which do not demand excessive physical labor. All the steps for the tillage of the soil and marketing of crops are comparatively easy, and the harder forms of labor fall to be done during the coolest season. As regards the general salubrity of the country, the low sickness and death rate, the testimony is most satisfactory. I will not give the data which have been gathered for the forthcoming census; suffice it to say they will go far to remove the popular error that Florida is to be classed among the unhealthy States. One of the oldest and most intelligent of the captains sailing on the St. John's River told me that during his twenty years' experience fevers had scarcely been known on his boat; that last summer, for instance, not a hand or officer had been ill with it. In the river towns, however, there are spring and autumn fevers, and septic diseases have occurred, which go to show that, with population, preventable sickness of a malignant type will come, as everywhere. There is a peculiarity in the topography of the river and lake towns which is well worth description, as it is almost universal or typical, and suggests a source of grave insalubrity, if not turned to good account before sore pollution follows population.

Almost every town and hamlet that I have seen on the shores of the rivers, and the borders of the lakes, stands on a ridge, or knoll. The consequence is that immediately back of every such town or hamlet there is a "sloo" or bayou, occasionally overflowed, but commonly marshy and sour, and the dumping-place for the rubbish and filth of the town, or not unfrequently the objective for the earliest attempts at sewerage. Near such suburbs the poorer classes of the population huddle, and form the foci of degradation and communicable diseases. This evil is beginning to be partially seen and corrected, and notably, as at Jacksonville, turned to good purposes. At this latter place a drainage canal is being built circumvallating the town, which, if well done, and scrupulously kept clean, will guard the future health and morals of the place. It is, as you well know, proverbial that moral and physical filth-diseases go together. What a blessing it would be to the world if those who lay the foundations of towns would so control their suburbs as to preclude, as by impregnable walls, the nastiness which clings to their skirts. One always passes the fine residences in towns and looks in through their windows with amazement that the occupants of the same can be so unconscious of the fact that in the hovels of their poor and ignorant neighbors are being generated the diseases which every breeze, and every passing unwashed human being, is the vehicle of. Why it is that every town has not its "Public Purposes Society" to study and remove the obvious causes of preventable disease, is a marvel passing strange. There is the hideous error everywhere believed, or ignorantly acted upon, that in some unexplained way filth becomes harmless when concealed in the ground or turned into running water. It will apparently take ages to teach men who build towns the truth that soil once polluted never cleanses itself, if the pollution saturates. And as we never know, except through the volcanic outbreak of disease, when such point of saturation is reached, why begin the dirty work at all, and incur the fearful risks? The hotels of Florida are generally excellent, and several of them are models of cleanliness and comfort. The water-closet of the Windsor Hotel, at Jacksonville, is itself a missionary enterprise. Mr. Orvis, the proprietor, may justly be classed among the benefactors of his race. He is said to have introduced broiled beefsteak and hair-mattresses into Florida, and his beneficent career is still going on.

Ever faithfully yours,

C. R. Agnew.

266 Madison Avenue, New York, December, 1881.

---

Mr. Beecher's Surgical Ability.—In a sermon delivered recently, Mr. Beecher said that, while he was not a surgeon, he felt sure that he could cut a man's leg off if necessary, for he knew how to tie up an artery and draw the flaps over. Blessed were the men who had a little of everything in them.

## THE EXPULSION OF INSECTS FROM THE EXTERNAL AUDITORY CANAL.

To the Editor of The Medical Record.

Dear Sir: In an article upon "The Removal of Foreign Bodies from the Ear," published in The Record of December 10th, the lecturer is reported to have said, "When flies and maggots gain entrance to suppurating ears, the case is one for simple treatment with the syringe, first using some agent which will kill the fly or maggot, such as carbolic acid, Labarraques' solution, or the like; after this the stream of warm water may be employed. An attempt to remove them with the forceps only makes them more lively, and increases the difficulty of their removal."

The question of the removal of living insects from the ear is so important that we cannot refrain from calling attention to a method first discovered by the late Dr. John Ellis Blake, of this city, and described by him in the history of a case published in the *Boston Med. and Surg. Journal*, vol. lxvi., p. 214, 1862, and entitled "Larvæ of the Common Fly in the Meatus Auditorius Externus." The patient had suffered for four or five days with hemorrhage from the ear, and most excruciating pain. Of his interview with him, Dr. Blake gives the following graphic description: "With difficulty, owing to the flow of blood and the involuntary movements of the patient, I was able to introduce a speculum into the meatus, and get a glimpse into the interior. What was my astonishment to find it tenanted by several maggots in full activity! The movements of these creatures against the sensitive structures of the ear was evidently the cause of the pain, and their excavations in feeding the cause of the hemorrhage. The least attempt to remove them by instruments was resisted by them, and as they were immediately set in motion, thereby wriggling against the membrana tympani, the agony caused the patient was too much for human endurance, and he could not be held in the chair. I consequently desisted from such attempts, remembering some experiments I once saw tried upon these larvæ, tending to show their extreme tenacity of life for a time, even when immersed in caustic substances. I wasted no time after a few trials with syringing, but catching sight of a conical ether sponge upon the table, it occurred to me that anæsthesia might do. The sponge was wet with sulphuric ether and held for a few seconds over the ear, when we had the satisfaction of seeing the maggots wriggle from the ear in great haste on removing it. On looking in but one could be seen, and a reapplication of the sponge soon caused him to come out for fresh air. The whole number removed was eight or ten, and as the larvæ were of good size, I can hardly see how they could have been packed away so deeply in the passage."

Since the appearance of Dr. Blake's article, the method has been used with great success, as I have been informed by him, in various parts of the tropics, where such accidents are of more common occurrence than in our northern latitudes. A case was related in a Spanish journal about two years ago, in which larvæ in the *frontal sinus* were promptly expelled by the inhalation of chloroform. Prof. J. Solis Cohen, also, in his work upon diseases of the throat and nose, alludes to the use of anæsthetics in such cases. Of course, this method would apply to the treatment of any cavity of the body which could be invaded by an insect, and if any doubt existed as to the vapor of these drugs being insufficiently diffusible to enter a remote sinus, the operation might be assisted by the use of the spray atomizer. This, however, would seldom be necessary. The value of Dr. Blake's suggestion is too obvious to need comment. In the hope that it may not be permitted to fall into oblivion,

I am, very respectfully yours,

D. B. D.

59 West Thirty-eighth Street, New York.

## DISLOCATED SPLEEN IN HYPOGASTRIC REGION IN A WOMAN—EIGHT YEARS DURATION.

To the Editor of The Medical Record.

Dear Sir: I report the following case on account, 1st, of its being unusual; and 2d, in order that some one of your many readers may suggest, if possible, some mechanical appliance that may keep this refractory and aberrant organ in its place.

I was called on Sunday, October, 30, 1881, to see Mrs. A. R——, white, a widow, aged about thirty-two years. She presented an anæmic aspect, and was badly nourished; was a serving woman in a gentlemen's clothing store. She informed me that she had a tumor which she wished me to examine and prescribe for; that it had been treated by physicians as an ovarian tumor, and as a uterine fibrous tumor; that it had existed for about eight years; that it varied in size; was painful at times, especially when enlarged; that it seemed to sympathize with her menstrual flow, becoming more painful and tumified at that time, and whenever she had fever. From its position, the finger of slander had been pointed at her, it having been said of her that she was pregnant.

Upon examination, I found a flat, irregular, insensible tumor in the hypogastric region; movable, except at its lower edge, which seemed to be caught behind the symphisis pubis, and between that and the anterior vaginal wall; it was sulcated on the upper left edge. When she lay on her right side the tumor dropped over to the right iliac region, and could be turned on its edge, and the left edge made to tilt up and forward, so that you could pass your fingers behind it by pressing on the abdominal walls. By examination per vaginam, a projection was felt against the anterior wall. Suspecting it was the spleen, I pressed this body upward with my right finger in the vagina, and pushed the abdominal tumor upward with my left hand, when the mass escaped from its mooring, and floated free in the abdominal cavity. Pushing it in, I soon got it into the left hypochondrium, and pulling up the ribs got its upper edge well under them. Now I had an enlarged spleen *in situ*. I suppose in its longest diameter it would measure six inches, and about four inches transversely. The vesicle tenesmus was immediately relieved, and has not appeared since. This was mechanical in its cause. Upon close questioning, I found that the swelling began in the left hypochondrium. I think the cause of the dislocation was corset-constriction about the waist, and muscular exertion due to her having to labor for her own and children's support. The dislocation was gradual. Under restorative tonics and antiperiodics she has much improved, and the spleen is reduced. But it will not stay in its place when she is erect and working. Can any one suggest any appliance that will free the mechanical indication.

Very respectfully, Benjamin H. Riggs, M.D.

Selma, Ala., December, 1881.

## NO CODE OF MEDICAL ETHICS NEEDED.

To the Editor of The Medical Record.

Sir: I read all the articles I see on Ethics with interest, because I began practice as a strict follower of the Code; but varied experiences, humiliating and otherwise, have led me to believe the best code is the golden rule of doing unto others as you would have them do unto you. If a doctor is a *gentleman*, his good breeding and honorable principles will be his guide, regardless of any printed code, and he will rarely do wrong to another, either physician or patient; but, if he happens *not* to be a gentleman, then rules will not influence his actions.

Members of the profession have wide latitude as to fees, for each one rates his own services. This is wise and proper; and likewise, they should be allowed to regulate their professional actions with as much latitude, being guided solely by their sense of propriety and justness. There are some homœopaths I would meet in consultation, for they are not wedded to infinitesimals, and are well educated and cultivated ladies and gentlemen. If they or I can learn from each other for the benefit of those afflicted by disease, I see no reason why we should not meet together.

I have met ignorant midwives and relieved their patients, and I should not hesitate to go anywhere and meet any one if I thought I could help relieve suffering.

There are various points springing up all the time, which, to my mind, no code can cover, which a man or woman of correct principles and education can settle satisfactorily for themselves.

If a doctor whose services are worth five, ten, or twenty-five times my own is used by me, justice would tell me I should not use him gratuitously.

If a doctor wishes to advertise himself directly or indirectly, I say let him do so; but if I do not admire that style, then I need not do so.

Let there be a law that every M.D. shall have a *classical* education, and shall be graduated *practically* as well as *theoretically*, by a *high* standard, free to practise according to the knowledge he thinks he has, without restrictions of codes, according to his own sense of propriety, and I believe those who now practise regardless of others, will diminish in numbers, and there will be a fraternal feeling among all the schools, highly conducive to the dignity of the profession and to the welfare of the laity. In conclusion, I would say I am out and out a *regular* in prescriptions.

Yours respectfully,

D. B. C.

New York, December 1, 1881.

---

The Electrical Bullet-Finder invented by Mr. Graham Bell, and used upon President Garfield with such signal lack of success, has been presented to the Académie des Sciences at Paris. The instrument is essentially the same as that described in the columns of the Record last summer. Two additional coils are added, however, which make the instrument more delicate. On October 7th, says the *Lancet*, an experiment was made, in the presence of Dr. Hamilton and others, on the person of Col. Clayton, who was wounded in 1862. The ball had passed through the articulation of the left clavicle. It was supposed to be lodged under the scapula, but by the new apparatus was readily found to be in front of and below the third rib.

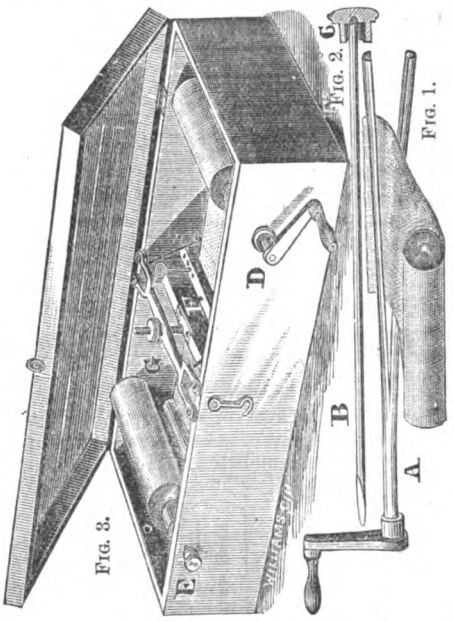
# New Instruments.

## A NEW APPARATUS FOR PREPARING PLASTER-OF-PARIS BANDAGES.

By WILLIAM JUDKINS, M.D.,

Surgeon to the Home for the Aged, Cincinnati, O.

One of the difficulties we have in making plaster-of-Paris bandages in any quantity, the profession well know, is the labor and tediousness, to say nothing of the dirt, with which the act is accomplished. To make light of one, and expedite the other, the accompanying cut and explanation will, I trust, make clear an idea on which some time and thought has been bestowed by the writer, with the result of having an apparatus that may be worked all day without fatigue, delay, or confusion. A brass tube (Fig. 1, A) six inches long by three-sixteenths of an



inch diameter, with a fine saw is slit lengthwise within an inch of its end, into which the handle is soldered. A solid brass pin (Fig. 2, B) one-eighth of an inch diameter five inches long, with a hollow brass cap C (sectional view) which, when fitted into the brass tube, the cap clasping the slit ends, produces a solid rod. Before using, the pin is withdrawn and the tube is introduced into the side of the box (Fig. 3, D). One end of the crinoline bandage on the pin E having been run under a bar near the bottom of the box, and through the gate of the regulator F, is inserted between the jaws of the tube, as shown in Fig. 1, and the latter is then carried through the opposite side of the box. The brass pin B is now slowly pushed through the tube and over the end of the bandage, its whole length clasping the extremity of the jaws in the cap. A pint or more of plaster is placed in the box at G, and the handle rapidly turned; the bandage, in its passage through the gate at F, has all superfluous plaster scraped from its surface, and passes on to the bar D with a coat of plaster

thoroughly impregnated in its meshes. As the gate in the regulator F is set at *any* height by a thumb-screw before commencing operations, the bandage may be charged of *any desired thickness*. Should any foreign material be in the plaster, which would tend to clog the free running of the bandage, there are, on the extreme sides of the regulator, rubber bands that will readily allow any such obstruction to pass. It is advisable when the tail end of the bandage presents at E to pin on a fresh one, and run the end under the bar and through the gate F, there it can be unpinned and the balance of the first bandage finished. After it is charged, the hollow capped pin is withdrawn on one side of the box, and the rod D on the other, the bandage falling to the floor of the box ready for use. From the numerous trials this apparatus has had by Messrs. M. Wocher & Son, of this city, who are the makers of same (and from whom the writer has received some valuable suggestions regarding it), and myself, I am confident that we *now* have an instrument which will prove a valuable addition to the armamentarium of the surgeon.

216 Race Street, Cincinnati, December, 1881.

## ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from December* 18, 1881, *to December* 24, 1881.

Alexander, R. H., Major and Surgeon. The leave of absence granted him in S. O. 215, September 19, 1881, from A. G. O., is extended one month. S. O. 285, A. G. O., December 17, 1881.

Jefferson Medical College.—The dean of this college writes to say that the medical class of that institution for this year is larger than that of last, thus correcting a statement quoted by us from the *Philadelphia Medical Times*.

Maternity Hospital, New York.—Dr. H. J. Garrigues, of this city, has been appointed Visiting Physician to the Maternity Hospital, vice Dr. W. T. Lusk, resigned.

Lunatic Asylum Reform.—The Legislative committee appointed to investigate abuses alleged to exist in many of the insane asylums in the State, as well as to report any legislation that may be found necessary to bring about improvement, met in this city December 15th. The session was devoted entirely to the examination of Dr. E. H. Chapin, Superintendent of the Willard Insane Asylum at Ovid. He testified that he had been Superintendent at the Willard Asylum since 1869, and had supervision of both chronic and recent cases of insanity. With regard to the employment of the patients at labor, he said that last summer 825 were thus employed, the largest number yet engaged in such a manner. It was found that the lunatics could do any kind of common farm and household work. They planted and cultivated potatoes, planted and reaped corn, harvested wheat, and cut hay. In the garden they took care of twenty-five acres of land on which vegetables of various kinds were raised. There was no compulsion whatever in this employment. The patients did as they were directed, either voluntarily or under the promise of a ration of tobacco. Assaults by one patient upon another have sometimes been reported, but there had never been any rebellion or serious violence of any kind because of the employment of the insane at such labor. They did not destroy the crops or implements, and it was found that occupation in the case of chronic patients gradually led them into a more rational mode of thought and action; they rested better at night, and were generally less boisterous. In fact, labor was found to be the best therapeutic agent that could be employed in such cases, and was better than medicine.

Dr. Chapin gave in detail his experiences during a four months' trip abroad, when he visited the asylums for paupers in Great Britain, France, Italy, and Belgium. In England he found the patients to be in better condition than here, and the whole system was superior in its results to that of America. The percentage of patients employed was much larger than in the United States. The males worked at trades in tailors' shops and shoe shops, and especially at weaving. The employment of women was also a marked feature in the foreign asylums. They sew and make up clothing for themselves and for the men, a piece of industry very rare in this country. In England the patients are removed in the day-time from the rooms they occupy at night to large rooms or wards, which removal is conducive to better discipline, and the development of better general health and industry among the inmates. In this country the patients are kept in small rooms or crowd the corridors, and there are none of the large rooms or wards that are used abroad as workshops. The architectural plans of the English asylums are also superior to those of like institutions in America. The percentage of patients employed at trades in the asylums visited by the witness was sixty-one, while in his own asylum the percentage was but twenty-six. In out-door work, however, American asylums can surpass the English. Mechanical restraints are abolished in England. Out of a total of fourteen thousand patients, he saw abroad but two who were restrained by mechanical devices. The necessity for such restraint does not appear to exist under the English system. Narcotic medicine is not so much used as it is here, but the number of attendants is greater, although they are prohibited in some cases from carrying a key or locking up the inmates. The doors are left unlocked, and even bars are removed from the windows, which the witness considered a great improvement, as the presence of such safeguards often excited the insane even more than the rational prisoner. The English attendants also are far superior to the American. While not more intelligent, they do their work better at much less pay, and are contented with their condition. Here it is very difficult to secure such attendance, or to obtain people who will remain as employés in an

asylum longer than from two to four years. Higher pay would not secure this desideratum.

The witness, being questioned as to suggestions which he could make regarding possible improvements in the present administration, said that the matter of facilitating the discharge of proper inmates should receive attention, and that changes might be made with a view of fixing more definitely the date of the certificate of admission, as to whether it reckoned from the time of the physician's examination or the completion of his affidavit. He thought that better results might be obtained than at present if the State Board of Charities and the Examiner in Lunacy worked together harmoniously, instead of laboring as if they were constantly invading the province of each other. One Commissioner in Lunacy was not sufficient for the 12,000 or more insane of the State, if his duties embraced the visitation and examination of the patients. Improvement might also be secured if there were some State board to lay down certain rules of management and plans of construction, which County Commissioners should be bound to respect and enforce. The confinement of patients in cellars or basement rooms, without proper light or adequate sized windows, should be prohibited. The asylums and rooms should further be regularly inspected by physicians. Something should be done also to afford immediate care of the insane who, while not paupers, are unable to obtain necessary medical treatment because of their inability to pay the rate charged by private institutions. At present there is no relief for such insane people, nor is there adequate accommodation for the insane poor at the public expense.

THE VIRCHOW CELEBRATION.—The sixtieth birthday of Professor Virchow, and the twenty-fifth anniversary of his professorship, took place at the Rathhaus, Berlin, on November 19th. The guests and the honors tendered him showed that his worth and genius were appreciated in all ranks and classes. About twelve hundred persons were present, including many ladies. Nearly all the Medical Faculty of Berlin were present. On the arrival of Virchow the band played a march from the "Tannhäuser," and the whole audience rose as he stepped on the platform. Councillor Friedel announced that contributions had flowed in from all parts of the civilized world, "from Archangel to Cadiz, from New York to Moscow," in aid of the endowment of an institution in honor of the great Professor, and Professor Stockvis, of Amsterdam, representing a Dutch committee which had forwarded a large sum with the same object, addressed him in an eloquent speech, in which he said: "You have raised on high the standard of science, the banner of humanity, the flag of free research, and this you have done with admirable modesty and consideration which have won for you all hearts—even those who do not agree with you on all points." The Director-General of the Royal Museum was present, but the royal family, who would have flocked to do honor to any one who had invented a new mode of man-killing, were conspicuously absent. An interesting deputation of four old men came from Schiwelbin, in Pomerania. After expressing the warm good wishes of their townsfolk, they stated their intention to place an inscription on the house where Virchow was born.

A number of other addresses were made from prominent scientific men, and from the delegates of various medical and scientific societies. Professor Virchow delivered an eloquent speech in reply. The affair concluded with a banquet.

THE SUMMONS AGAINST DR. FERRIER.—The *British Medical Journal*, under the head of "Obituary," gives a full account of the proceedings against Dr. Ferrier on account of his vivisections. The summons was dismissed. The charge caused much excitement among the English medical men, and has brought the subject of cerebral localization into great notice. The affair has ended happily for science, and has not been without good in drawing attention to many important facts in nerve physiology and pathology.

DR. WOOLSEY JOHNSON has been appointed one of the City Health Commissioners, in place of Dr. E. G. Janeway, resigned.

AMERICAN PORK TO BE PROHIBITED AGAIN.—In the Chamber of Deputies, December 13th, M. Gaudin questioned M. Rouvier, Minister of Commerce, in regard to the importation of American pork. M. Gaudin said that it ought not to be left to the importers themselves to take the necessary steps to prevent the importation of infected meat. After some discussion, he submitted a bill embodying the former prohibitory decree which the Government had withdrawn.

THE STATE BOARD OF HEALTH met at Albany December 13th, and made up its annual report. The reports of the analytical chemists on food adulteration were also read and considered.

DR. D. WARREN BRICKEL, a prominent physician of New Orleans, died December 12th, at the age of fifty-four years.

DR. THOMAS S. CURTIS, one of the surgeons to the Massachusetts General Hospital, in Boston, died suddenly December 12th, at the age of forty years. He was graduated at Harvard and in Paris, and was a member of many medical societies at home and abroad.

MR. HENRY BERGH has written a long letter to the President of the City Health Board, inveighing against the practice of vaccination. The letter contains a number of incorrect statements, and some very crude reasoning.

LISTERISM, according to Lawson Tait, "is one of the largest, best-blown, and most attractive bubbles ever displayed to a surgical audience."

The same authority asserts, with much flourish, that the next case of peritonitis to which he is called, even if it be puerperal, he will advise, and perform, if allowed, abdominal section, and will cleanse out the cavity and drain it.

Now, if Mr. Tait himself would only be the next case!

The other side of the Lister question is given by M. Lucas-Championnière, who claims for it the following results: The disappearance of wound-accidents, even in the worst circumstances; a regularity in repair hitherto unknown; surgery without suppuration; union by first intention, habitually and without danger; such rapidity in healing as to surpass all anticipation; the possibility and safety of operations hitherto considered dangerous and unjustifiable.

EXCISION OF THE THYROID GLAND, which may be classed among the notable operations of surgery, was recently performed with success by Mr. Walter Whitehead, at the Royal Manchester Infirmary. The patient, a woman, aged fifty-one, had had a small thyroid tumor for thirty years. In the past five years it had begun to grow rapidly, causing dyspnœa, and threatening strangulation. The tumor

was enucleated and removed with but very little loss of blood. It seemed to be fibro-cystic in character. The patient made a good recovery, except for an aphonia produced by the operation.

A Case of Syphilis Inoculated by Skin-Grafting was reported by M. Féréol at a meeting of the Société Médicale des Hôpitaux, Paris.

An International Sanitary Exhibition at Berlin.—An international exhibition of objects relating to public health and life-saving appliances will be held at Berlin in 1882, from the 1st of June to the 1st of October. A special invitation is extended to exhibitors in the United States. The Executive Committee have appointed Mr. H. W. Fabian, of New York, as special commissioner to receive applications and to furnish all necessary information. The exhibits are divided into the following sections:

A.—*Department of Public Health.*—This will include, among other things, soil and atmospheric air; removal of sewage, excrements, and garbage; providing towns with water; public baths; public instruction; dwellings; food products; clothing, and treatment of the skin; preventing contagious diseases; hospitals, medical establishments, and infirmaries; burial of the dead, vaults and morgues; veterinary department.

B.—*Department of Life-Saving*, which will include ambulances, hospitals, barracks and hospital-ships, and apparatus for taking care of the wounded in war.

Mineral Waters in Malaria.—In a communication received from Dr. S. E. Whiting, of Saratoga Springs, he claims that decidedly favorable results are obtained by the use of mineral water in malaria. His observations seem to extend over considerable space of time during the growing prevalence of the disease.

He also maintains that the water in its *best* effect is *constitutional* and *elementary* in its tonic action on the system; a *builder-up* and a *repairer* of *wasted energies* in our organism. He observes that after a few weeks' use of the water—sometimes sooner—*well-marked periodicity* of chills and fever are developed that had never existed; that the system seemed *toned up* by its use, and brought within the reach and influence of quinine and other remedies that had *failed* before.

He states that the development of these *characteristics* of the disease are the first *evidences* of *returning health*, and are proofs of the strong alterative effect as well as its powerful *eliminating* properties.

This result is not obtained by the spasmodic drinking of large quantities of mineral water, but by persistent *daily alterative* doses after a short course of active catharticism.

Treatment of Locomotor Ataxia by Training and by Mechanical Vibrations.—Dr. J. Mortimer Granville (*Practitioner*) recommends a careful and persistent training of the "muscular sense" in ataxia as a remedy for the loss of co-ordination. He would have them first learn to stand for a quarter of an hour, then half an hour a day, with the eyes closed Then they must be gradually taught to walk with the eyes closed. Dr. Granville is confident that such a process will be very effectual, but cites no cases in proof.

He also says that marked benefit seems likely to attend the use of mechanical vibrations applied to the spine.

Dr. Granville has an ingenious mind, but in the present case he seems to be writing from his closet.

A New Ophthalmic Journal.—The *Ophthalmic Review* is the title of a new monthly journal, edited by Drs. Karl Grossman and Priestley Smith, and published by G. & A. Churchill, London. The journal presents a good appearance; a large part of the contents consists of critical reviews.

Prizes Offered by the French Association Against the Abuse of Tobacco.—The Association has already earned a good reputation for the earnestness, yet moderation, with which it treats the tobacco question, and aims to establish, on a scientific basis, the evils growing not from the use, but the misuse of tobacco.

For the year 1881, the society offers the following prizes:

N° 2. — Prix Médical. — Quelle est l'influence du tabac sur la marche de la grossesse et sur la lactation chez les femmes qui font usage du tabac, qui en respirent la fumée, ou qui travaillent à sa manipulation. Présenter des observations recueillies sur les personnes, et, s'il est possible, des expériences chez les animaux. — Deux cents francs.

N° 3.—Prix fondé par M. le Dr. A. Berthrand.—Déterminer, par des considérations psychologiques, avec faits bien observés à l'appui, l'influence que l'habitude excessive du tabac détermine sur le *moral*, le *caractère* et les *rapports sociaux* des fumeurs. The prize consists in books to the value of about two hundred francs, and bronze medal.

Jaborandi in Croup has been successfully used by Dr. W. N. Ames, who reports his case in the *Medical and Surgical Reporter*.

The German and Swiss Universities.—The *Deutscher Universitäts-Kalender* for 1881–82 gives the following official statistics: In the winter term of 1881–82 the twenty-one German universities have 1,930 teachers. Of this number 730 are regular professors, 794 clinical or assistant professors, 50 emeritus professors, 466 assistants or privatdocents, and 45 tutors. In the summer term there were in all 22,612 students, among which 20,846 were regularly matriculated, while 1,766 were only entitled to attend lectures; 4,883 were students of medicine and pharmacy. Their distribution was as follows: Berlin, 576; Bonn, 187; Breslau, 295; Erlangen, 113; Freiburg, 300; Giessen, 101; Göttingen, 151; Greifswald, 316; Halle, 190; Heidelberg, 147; Jena, 85; Kiel, 119; Königsberg, 175; Leipzig, 455; Marburg, 158; München, 545; Rostock, 60; Strassburg, 171; Tübingen, 164; and Würzburg, 473.

At the three Swiss universities, 240 teachers are employed. Of this number 112 are regular professors, 33 assistant or clinical professors, 6 emeritus professors, 90 privatdocents, and 9 tutors. There were 1,135 students, of which number 404 were studying medicine, with the following distribution: Basel, 100; Berne, 148; and Zürich, 156.

Dr. E. G. Maupin, Acting Physician-in-Chief to the State Emigrant Hospital on Ward's Island, has resigned.

The Man who Sells Bogus Mucilage.—A man is visiting physicians' offices selling "Compound Mucilage" in cakes or tablets. The article is utterly worthless, becoming in two or three days dry and hard. In its fresh, moist condition, as offered for sale, it is apparently desirable, and nearly every one is deceived by it.

Impure Milk.—Nineteen persons have been convicted for selling impure milk.

# INDEX.

A

Abbe, Dr. Robert, removal of catheter from the bladder, 705.
Abdomen, bursting cysts of the, 442; dermoid cyst of, 683; exploratory puncture of, 439; gunshot wound of, 139, 611.
Abernethy on table-hygiene, 300.
Abscess, 67; hepatic, 26; in the chest, discharge of a head of rye, 305; of the broad ligament, 553; pelvic, 440; psoas, trephining the ilium for, 628.
Absinthe, catalepsy from the use of, 65.
Acid, boracic, in catarrh of the bladder, 375; boracic, in aural disease, 729, 749; carbolic, and anthrax, 308; carbolic, *versus* eucalyptol, 270; hydrobromic, 545; nitrous, as a disinfectant, 293; orthoboric, 729; oxalic, poisoning by, 529; salicylic, dry dressing with, 220.
Aconite, 335.
Aconitia, resistance of tabetic patients to, 22.
Adaptability, mental, in scientific work, 725.
Addison's disease, 246, 535.
Adenitis and angioleucitis, 5.
Adenoma of the mamma, 384.
Adulterations of food, 195, 279.
Adhesions, pelvic, forcible elongation of, 441.
Adjuvants, 647, 668.
Advertisements, misuse of, 548; quack, and *The Popular Science Monthly*, 671.
Esthetics and cathartics, 695.
Agnew, Dr. C. R., Florida in winter, 721; water transportation in Florida, 751.
Agnew, Dr. D. Hayes, lithotomy in children, 681.
Ainsworth, Dr. F. E., foreign body in the bladder, 64.
Ainsworth, Dr. F. C., hypodermic medication, 614.
Albany College of Pharmacy, 390.
Albumen, and sugar in the urine, 407; water of, 700.
Alcohol, 378; in therapeutics, 653; physiological action of, 69; use and abuse of, 105.
Alcoholism, acute, simulating hydrophobia, 28.
Alimentation, compulsory, 628.
Alkaloids, the cinchona, 25.
Allochiria, 54, 434.
Alumni Association, of the Albany Medical College, 389; of the University of the City of New York, 700.
Alumni associations, 14.
American Academy of Medicine, 352, 411, 520, 527, 582.
American Association for the Advancement of Science, 295.
American Gynecological Society, 381, 386, 438.
American Neurological Association, 17.
American Ophthalmological Society, 168, 215.
American Otological Society, 168.
American Public Health Association, 644, 671.
American Surgical Society, 322.
Ammonia, in pulmonary diseases, 573; intravenous injection of, 53.
Amyl, nitrite of, 181; nitrite of, as a cardiac stimulant, 406; nitrite of, in chordee, 340.
Anatomy, pathological, 55.
Anæsthesia, local, 389; local, and sea-sickness, 531; local, of the larynx, 69; tabetic, 182.
Anæsthetic car, an, 222.
Anæsthetics and cataract operations, 215.
Anderson, Dr. Charles, epilepsy followed by apoplexy, 484.
Aneurism, and the elastic bandage, 242; of the abdominal aorta, 486; of the thoracic aorta, 717; arteriovenous, 159; cirsoid, 551, 558; of aortic valve, with rupture, 344; of both vertebral arteries, 354; of the heart, 313, 362; of the innominate, 717; of the pulmonary artery, 495; of the thoracic aorta, galvano-puncture, 613; popliteal, 115, 485; spontaneous, of the common carotid, 416; subclavian, treated by needling and galvano-puncture, 358.
Angioleucitis and adenitis, 5.
Angio-sarcoma, 136.
Ankles, weak, aid in treatment of, 309.
Annual Report of the Marine Hospital Service, 448.
Anteflexion, in the etiology of dysmenorrhœa, 728.
Antiperiodic, the spider as an, 385.
Antiseptic, 448.
Antiseptics, at Billroth's clinic, 387; in midwifery, 325; in ocular surgery, 328; in the treatment of wounds in the field, 333.
Antivaccination Congress, International, 585.
Anthrax, and injection of carbolic acid, 308.
Aorta, abdominal, aneurism of, 486; thoracic aneurism of, galvano-puncture, 613.
Aphasia, intermittent, 462.
Aphorisms, obstetric, 419.
Aphthongia, 489.
Apomorphia in diseases of children, 290.
Apoplexy, following epilepsy, 484; spinal, 553.
Apparatus, convertible surgical, 12.
Arterial tension, in Bright's disease, 608.
Arteries, condition of, after death, 668; inflammation of, 12; vertebral, aneurism of both, 354.
Artery, common carotid, aneurism of, 416; femoral ligation of, for wound of the thigh, 636; pulmonary, aneurism of, 495; pulmonary, functional murmur in, 381; splenic, blood from, 721.
Arthritis, gonorrhœal, 655.
Ascites, 125; in childhood, 377.
Aspiration, in the treatment of buboes, 408.
Asthma, erythroxylon coca in, 644; neurotic theory of, 387.
Astigmatism, 179.
Asylum reform, 380, 754.
Atheromata, 183.
Atkinson, Dr. Wm. B., notice of book by, 690.
Atmosphere, deterioration of, in mines, 711.
Atrophy, progressive muscular, 433.
Atropia-poisoning, and pilocarpia, 41.

Attendance, compulsory clinical, 54.
Audiphone, Rhodes', 392.
Auricle, disarticulation of, for the removal of a foreign body, 219.
Auricles, cardiac, do they actively contract? 94.
Auscultation and percussion, 248.
Automatism, in an epileptic, 733.
Avulsion, fractures produced by, 108.

B

Bache, Dr. Benj. Franklin, obituary notice, 557.
Baginsky, Dr., notice of book by, 690.
Balfour, Dr. Francis M., notice of book by, 660.
Ball, difficulty in finding one in a dead body, 476; difficulty of finding one when it has penetrated a cavity in the human body, 725; how to extract the, 252.
Ballery, Dr. G. H., three twin-labors in one day, 541.
Balls, concerning the finding of, in cavities, 669.
Baltimore Medical College, 672.
Bandage, the elastic, in the treatment of aneurism, 242.
Bandages, easy way to roll, 84; new apparatus for preparing plaster-of-Paris, 753.
Bartholow, Dr. Roberts, notice of book by, 271, 494.
Barwell, Dr. Richard, notice of book by, 271.
Beard, Dr. Geo. M., a word for, 446; another word for, 695; notice of book by, 296; the medical use of statical electricity, 372; trained subject of, 641.
Beckwith, Dr. F. E., 680.
Bedside instruction, 742.
Beer, what it does in India, 280.
Belfield, Dr. Wm. J., hospital report, 571.
Belladonna, poisoning of fowls by, 28.
Bellevue Hospital, 346; State Charities Aid Association on, 728.
Benedikt, Moriz, notice of book by, 296.
Benzoin, tinct. co. of, in erysipelas, 626.
Bermingham, Dr. E. J., notice of book by, 100.
Bert, Dr. Paul, 178.
Bigelow, Dr. Horatio R., the trade-mark system, 162.
Bioplasson doctrine, 639.
Birth-marks, 535.
Bismuth, phosphate of, 420.
Bites of serpents, permanganate of potash in, 656.
Bladder, chronic inflammation of, 661; a supplementary, 475; and urethra, absorptive powers of, 377; catarrh of, boracic acid in, 375; expansion of, as a complication of laparotomy, 443; extraction of stone from, 243; foreign body in, 64; foreign body removed from, 638; laparotomy in wounds of, 712; lateral displacement of, 606; perforation of, by dermoid cysts of the ovary, 572; spasm of, 375; urinary, total extirpation of, 291.
Bland, Dr. Wm. J., 586.
Blindness, in Spain, 670.
Bliss, Dr. D. W., report of the case of President Garfield, 393.
Blood, effect upon, produced by hemorrhage, 306; peritoneal transfusion of, 390; transfusion of, 639.
Blood-vessels, treatment of injuries of, in the field, 334.
Board of Health, of Brooklyn, 430; of Cincinnati, 517.
Bone, intermaxillary, the human, 241.
Bosworth, Dr. F. H.; Jarvis' operation: its relation to nasal catarrh, 29.
Bougie, urethral, 643.
Boylston medical prize, 165.
Bradfield, Dr. J. Naylor, 391.
Brain, human, weight of, 682; left cerebral hemisphere of, destructive lesion, 19.
Brain-exhaustion and worry, 351.
Brains, of criminals, 261.
Breast, cysto-sarcoma of the, 362; excision of, for eczema of the nipple, 125; female, osteo-chondroma, 161.
Brickel, Dr. D. Warren, notice of death of, 755.
Briddon, Dr. Chas. K., extirpation of the lower end of the rectum, etc., 145.
Bright's disease, 247; iodide of potassium in the etiology of, 435; the early diagnosis of chronic, 607.
British Medical Association, 139, 270, 272.
Bromides, how to use them, 21; the, in sea-sickness, 214; the, in travelling, 272.
Bromine eruption, in a nursling, 599.
Bronchus, a tooth in a, 570.
Bronson, Dr. E. B., the action of mercury in syphilis, 505.
Bruns, Victor von, notice of book by, 660.
Brush, Dr. E. F., kumyss, 673; milk, 149; one mode of improving cow's milk for human food, 539; skimmed milk as an article of food, 459.
Buboes, treated by aspiration, 708.
Buchanan, "Dr.," 474
Bucklin, Dr. C. A., astigmatism, 179.
Bucknill, John Charles, another word for Dr. Beard, 695.
Buffalo General Hospital, 485.
Bullet, deflection of the, 448; instruments for the extraction of, 275; the lesson of the, 436.
Bullet-finder, electrical, 758.
Bunce, Dr. William, an apparatus for extension and counter-extension, 723.
Bureau, a governmental veterinary, 491.
Burn, deformity of hands from, 605.
Byford, Dr. Wm. H., notice of book by, 522.

C

Caillé, Dr. A., automatic trachial retractor, 724.
Calabar bean, in traumatic tetanus, 319.
Calendula officinalis, in aural disease, 729, 749.
Calculi, vesical, renal, and biliary, 159.
Calculus, nephritic, 634; removal by rapid dilatation of the urethra, 348; renal, hydrangea in, 652, 659; scrotal, 519; tonsillar, 523; urinary, 638; vesical, 403; vesical, operations for, 31.
Calomel, and soda, 28.
"Can a man graduate without having seen a case?" 49, 54.
Canal, aural, substitutive membrane in, 461.
Cancer, Chian turpentine in, 105; gastrotomy for, 387; mammary, 706; of the pylorus, 366; of the stomach, 634; of the thyroid body, 303; primary, of the pancreas, 518; primary of the liver, 362; traumatic origin of, 75.
Carbolic acid poisoning, after amputation of the thigh, 151.
Carcinoma, of the mamma, 384.
Cardiac rhythm, "galloping," 97.
Caries, novel method of treatment, 153; of the petrous portion of the temporal bone, 633; of the spine, diagnosis of, 348; of the teeth and pregnancy, 416.
Carpenter, Dr. Wm. B., notice of book by, 353.
Carreau, Dr. J. S., adenitis and angioleucitis of the pelvic cellular tissue, 5.
Carrier-pigeons, 504.
Cartilage, primordial, of the human skull, 241.
Castle, Dr. F. A., adjuvants, corrigents, etc., 647.
Castration, for dementia, 84.
Casts, renal, 420.
Catalepsy, from absinthe, 64.
Cataract, and electricity, 218.
Cataract operations, and anæsthetics, 215.
Catarrh, hypertrophic nasal, 479; nasal, 259; nasal, relation of Jarvis' operation to, 29; naso-pharyngeal, indications for treatment, 147.
Catgut, carbolized, for sutures in laceration of the cervix uteri, 675.
Cathartics, and æsthetics, 695.
Catheter, Eustachian, 82; urethral, removal from the bladder, 705.
Cattle commission, a national, 448.
Cavities, serous, fresh and dead tissues in, 41.
Cell, the decidual, and pregnancy, 292.
Census, of medical practitioners in the United States, 532.

Cerebellum, tumor of, 719.
Cervix uteri, carbolized catgut ligatures for laceration of, 675; laceration of, 497, 737; surgery of, 324.
Chambers, Dr. T. R., a tooth in a bronchus, 570.
Chantreuil, M., notice of death of, 194.
Chapin, Dr. C. V., notice of book by, 271.
Chaulmoogra oil, leprosy, 156.
Chicago, as a homœopathic medical centre, 389.
Chicago Medical Society, 130.
Childhood, a hitherto undescribed disease of, 181.
Children, growth and weight of, 224; sanitary care and treatment of (five essays), 495.
Chill, malarial, 627.
Chinoidine, borate of, 420.
Chloasma, uterine, 535.
Chloral, hydrate of, in cardiac disease, 629; in dysentery, 94; in strychnia-poisoning, 306; and glycerin, in diphtheria, 112.
Chlorosis, 408.
Cholecystotomy, 433.
Cholera morbus, epidemic, 417.
Chordee, nitrite of amyl in, 340.
Chorea, acute, 420; and rheumatism, 327; heart-symptoms of, 462; in the dog, 47; major, 22; mental disturbance in, 140; subcutaneous nodules in, 327.
Choroid, sarcoma of, 158.
Chromidrosis, 153.
Cigarettes, 223.
Circulation, cardiac, Brücke's theory disproved, 308.
Cirrhosis of the liver, 531.
Clarke, Dr. J. P. J., notice of death of, 699.
Clavicle, dislocation of acromial end, 734; necrosis of, 661; subperiosteal, removal of, 661.
Cleborne, Dr. C. J., spicular tongue-depressor, 415.
Club-foot, 67, 189, 303, 542.
Clysters, Zulu, 722.
Cocoa, for morphinism, 392.
Code of Medical Ethics, 753.
Coffee, action of, on the stomach, 387; what it will do, 280.
College of Physicians and Surgeons of Chicago, 672.
Colles' fracture, mechanism of, 107, 131.
Color-blind, peculiar look of the, 216; law, Massachusetts, 53.
Color-blindness, 329.
Cook County Hospital, 123.
Compression, digital, in the cure of aneurism, 416.
Conception, 543.
Conchinin, antipyretic action of, 153.
Conia, bromohydrate of, 69.
Conjunctiva, foreign bodies on, 421.
Conjunctivitis, epidemic catarrhal, 113.
Connecticut State Medical Society, 22.
Consultations, homœopathic, 528, 615.
Consumption, curious specific for, 305; pulmonary, in the young, 383.
Consumptives, in the Adirondacks, 387.
Contagia, preventing home, 251; prevention of, in schools, 715.
Convalaria, tincture of, in paroxysmal cardiac palpitation, 153.
Convalescents, home for mental, 222.
Cord, spinal changes in, in infantile paralysis and progressive muscular atrophy, 433; umbilical, hernia of, 376; vocal, sanguineous tumor of the right, 629.
Cornea, foreign bodies on, 421.
Corrigents, 647, 668.
Cough, without phthisis, 55.
Coulson, Dr. W. J., notice of book by, 353.
Cramer, Jennie, the case of, 296.
Cranium, gunshot wound of, 485.
Crania, human, in relation to race, 240.
Crawcour, Dr. J. L. dilator for stricture of the œsophagus, 163.
Creighton, Dr. Charles, notice of book by, 494.
Cremation, 168; in Denmark, 56.
Criminals, brains of, 261.
Crothers, Dr. T. D., clinical studies of inebriety, 341, 427; the trance state in inebriety, 561.
Croton water, impurities of, 28.
Croup, treated by introduction of a catheter from the mouth, 379; jaborandi in, 756.
Curare, action of, on the motor-nerve endings, 49; and motor-nerve endings, 138.
Curtis, Dr. Thomas S., notice of death of, 755.
Curvature, spinal, treatment of, 322.
Cutaneo-venous tumors, 683.
Cyrtometer, 164.
Cyst, dermoid of the abdomen, 683; double ovarian, 357; spinal death from, 391.
Cysto-sarcoma, of the breast, 362, 563.
Cysts, bursting of the abdomen, 442; ovarian, results of incomplete removal of, 685.

D

Dale, Dr. Edward T., notice of death of, 503.
Dalton, Dr. John C., position of the embryo in the fowl's egg, 589.
Damainville, Dr. L., concerning the finding of balls in cavities, 689
Dana, Dr. C. L., cases which do not illustrate reflex disturbances from genital irritation, 569; the physiology of the phenomena of trance, 85.
Dandridge, Dr. N. P., popliteal aneurism, 115.
Danforth, Dr. Isaac N., chronic catarrhal pyelitis, 89.
Darwinism, and the extinction of great men, 388.
Day, Dr. Wm. Henry, notice of book by, 300.
Dayton, Dr. Wm. A., effects of the abuse of the sexual instinct in females, 593.
Deafness, sudden, from syphilis, 517.
Death, sudden, without assignable cause, 663.
Death-rate, our increased, 156.
Deaths, six months', in New York City, 165.
Deflection, of the bullet, 448.
Delavan, Dr. D. Bryson, primary epithelioma of the larynx, 625.
Delphinium Ajacis, 655.
Dementia, castration for, 84.
Depressor, a vaginal tongue, 415, 698.
Dermatology, 251.
Derr, Dr. E. Z, popliteal aneurism, 485.
Development, 242.
Diabetes insipidus, 589.
Diabetes mellitus, acute, 710; affections of the pancreas in, 657.
Diagnosis, an amusing, 463.
Diarrhœa, infantile, and sea-air, 139; of phthisis, treatment of, 308.
Diet, for gout, 640.
Digitalis, indications for the use of, 739; not a cardiac stimulant, 560; value of, 280.
Dilatation, rapid, for extraction of vesical calculus, 403.
Dilator, a new, 723.
Diphtheria, 190, 258, 476; chloral hydrate in, 112; pilocarpine in, 153, 598.
Diphtheritic membrane, pepsin a solvent of, 616; contagious nature of, 740.
Diplomas, bogus; Spain *versus* the Buchananites, 137; dental, in France, 559.
Dipsomania, practical treatment of, 55.
Disease, a hitherto undescribed, of childhood, 181; aural, acid boracicum in, 729, 749; influence of food in the spread of, 251; intracranial, and ophthalmoscopic conditions, 329; prevention of, by inoculation, 99; renal, 249; zymotic, influence of milk in the spread of, 250.
Diseases, communicable, incubation of, 55; contagious, and pet animals, 530; contagious, prevention of the spread of, 28, 727; of the nervous system, methods of diagnosis in, 617, 701; ergot in, 503; of children, apomorphia in, 290; prevention of diffusion of contagious, 250; specific, and minute organisms, 264.

Disinfectant, a new, 222; nitrous acid as a, 293; nitrous ether as a, 283.
Disinfectants, relative powers of different, 294.
Disinfection, by heat, 40.
Ditana digitifolia, 420.
Doctor, chances of the, 306; funeral of the dead, 734.
Doctors' signs, 185.
Dog, chorea in the, 47.
Donkin, H., Dr. Beard's trained subject, 641.
Drainage, in rupture of the uterus, 290.
Drake, Dr. F. R. S., 195.
Draper, Dr. W. H., secondary syphilis, 431.
Dunglison, Dr. R. J., the American Academy of Medicine, 527.
Dynanometer, a new foot-, 21.
Dysentery, chloral hydrate in, 95.
Dysmenorrhœa, anteflexion in etiology of, 728; electricity for, 280; membranous, 597.
Dyspepsia, cerebral symptoms of, 588.
Dyspnœa, quebracho in, 304, 559.

E

Ear, acid boracic and calendula in the treatment of disease of, 729, 749; discharge from President Garfield's, 467, 472; effect on, of high atmospheric pressure in tunnel-construction, 137; croupous inflammation of the middle, 95; middle, epithelioma of, 219; removal of foreign bodies from, 645, 702.
Eaton, Dr. Frank B., dislocation of the acromial end of the clavicle downward and backward, 734.
Echinococcus, of the mammary gland, 543.
Eclampsia, puerperal, morphine in, 726.
Eczema, of the nipple, 125.
Edson, Dr. Benj., hydrangea in renal calculus, 652.
Education, preliminary, 418.
Edwards, Dr. Joseph F., notice of book by, 298.
Edwards, Dr. Emma Ward, undeveloped uterus, with apparent absence of ovaries, 653.
Effusion, pelvic, resulting in abscess, 440; pleuritic, 683.
Egg, how to tell the age of an, 152.
Electricity, and cataract, 218; for dysmenorrhœa, 280; in labor, 417; new current of induction, 62; recent progress in the medical uses of, 98; static induced, 20, 21, 317, 372; static, as a galactagogue, 700; static, in hysteria, 713; in impotence, 592.
Electrolysis, epilation in, 105; in the treatment of mammary cancer, 706.
Electro-massage, 140, 616.
Elephants, fecundity of, 478.
Elsberg, Dr. Louis, 700.
Embalming, new method of, 739.
Embolism, cerebral, 292; fatty, 69.
Emphysema, of the eyelids and orbit, 683.
Empyema, 374; surgical treatment of, 326; treated by aspiration and incision, 346; treated by incision, 345.
Embryo, human, normal characters of, 240; position of, in the fowl's egg, 589.
Emmet's operation, proper limitation of, 78.
Enchondromata, 519.
Enchondroma, of the larynx, 407.
Endocarditis, progressive obliterating, 408; septic, 746; ulcerative, 361.
Enterectomy, 572.
Enteritis, membranous, 292.
Epilation, 389; in electrolysis, 105.
Epilepsy, 121, 261; remarkable automatism in, 733; cured by enucleation of the eye, 722; early recognition of, 141, 169; followed by apoplexy, 484; gastric, 408; gulf-weed in, 726; symptomatic, 252; trephining in, 277.
Epileptics, insane, peculiar effect of bromide of potassium upon, 18.
Epiplocele, 77.
Epithelioma, at the inner angle of the orbit, 218; new treatment for, 48; of the lip, 75; of the lower lip, 303; of the middle ear, 219; of the neck, 691; of the penis, 303; of the tongue, 302.
Ergot, in sea-sickness, 389, 532; therapeutic use of, in nervous diseases, 503.
Eruption, typhoid, 252.
Erysipelas, compound tincture of benzoin in, 626; without puerperal peritonitis, 443.
Erythroxylon coca, in asthma, 644.
Esthiomene, 442.
Ether, deaths from, 28; ignition of at an operation, 716.
Ethics, medical, no code of needed, 753.
Ethiops mineral, in pertussis, 414.
Eucalyptol *versus* carbolic acid, 270.
Eustachian, catheter, 82; tube, functions of, 331.
Everett, Dr. J. Turner, the physiological treatment of pneumonia, 283.
Evolution, the hypothesis of, and sanitary administration, 365, 424.
Ewald, Dr. C. A., notice of a book by, 522.
Excision, of joints, 244.
Exhibition, International Sanitary, 266.
Exhilarant, a new, 112.
Exophthalmos, pulsating, 218.
Exostoses, etiology of aural, 330.
Experimental investigations regarding the pathology of malaria, 744.
Expert testimony for the prosecution in Guiteau's case, 743.
Extension and counter-extension, 723.
Extremities, lower, instrument for measuring, 164.
Eyelids, emphysema of, 683.
Eyes, inoculation of, for pannus, 4; localization by, 724; weak, in the public schools in Philadelphia, 217.

F

Fan, the Japanese otacoustic, 286.
Fat, in the urine, 627.
Feet, inverted, aid in treatment of, 309.
Fellows, Dr. H. S., notice of death of, 388.
Femurs, fracture of both in a child, 252; gunshot fracture of, 638.
Ferrier, Dr., 671, 755.
Fever, enteric, etiology of, in India, 334; hay, 222, 572; intermittent, 392; malarial, and wounds, 573; splenic, vaccinating for, 583; surgical scarlet, 327; typhoid, alcohol in, 316; typhoid, and sewerage, 252; typhoid, at Rugby, Tenn., 371; typhoid, eruption of, 252; typhoid, from milk, 336; typhoid, in children, 54; typhoid, intestines illustrating aggravated lesions of, 524; typhoid, sudden death in, 657; typhoid, warm bath, 55; typhus, 189, 336; urethral, 151; yellow, 112, 221, 388, 672.
Fevers, eruptive, 262.
Fibroid, multiple uterine, 357.
Fibro-sarcoma, of the trachea, 543.
Filaria sanguinis hominis, 571.
Finger-nails, atrophy of, 553.
Fish, trichinæ in, 391.
Fitch, Dr. James D., notice of death of, 195.
Fleming, Dr. George, notice of book by, 101.
Flint, Austin, M.D., LL.D., 84.
Florida in winter, 721; water transportation in, 751.
Flower, Dr. Wm. H., notice of essay by, 690.
Fluorides, the, in medicine, 168.
Fomentations, ready method of preparing, 82.
Food, adulteration of, 195, 279; cow's milk for, 539; skimmed milk as an article of, 459.
Forceps, electrical, 195, obstetric, axis-traction of the, 445; Tarnier's, 323.
Foreign bodies, action of, in the eye, 328; removal of, from the ear, 645.
Forests, mountain, effect of removing, 531.
Foster, Dr. M., notice of book by, 604.
Fothergill, Dr. J. Milner, notice of book by, 414.
Fox, Dr. Geo. H., notice of work by, 157.

Fracture, Colles', mechanism of, 107; gunshot, of the femur, 637; of both femurs, in a child, 252; of the skull, 633.
Fractures, spontaneous, due to syphilis, 684.
Fredericks, Dr. C. C., hospital report, 485.
French Association for the Advancement of Science, 54.
Fresh air habit, the, 560.
Friction-sound, pseudo-pericardial, 416
Friedrich, Dr. J. J., on Guiteau's insanity, 556
Fumigation, local mercurial, 588.
Function, cerebral, localization of, 332.

G

Galactagogue, static electricity as a, 700.
Gall-bladder, rupture of, 587.
Galvano-puncture, in aneurism of the aorta, 613.
Gangrene, pleural, 418.
Gardner, R. W., hypophosphites *versus* phosphites, 696.
Garfield Hospital, 530.
Garrigues, Dr. H. J., 754; a vaginal depressor, 698.
Gastralgia, nervous, 627.
Gastrostomy, 739.
Gastrotomy, for cancer, 387; for extra-uterine pregnancy, 519; successful, 655.
Gelsemium in neuralgia, 119.
Genital irritation, 569, 575, 576.
Genital renovation, 440.
Genu valgum, 172, 187, 326.
Germ theory, 231.
Gilchrist, Dr. J. G., notice of book by, 271.
Gillette, Dr. W. P., how to prevent sediment in Magendie's solution, 385.
Girdner, Dr. John H., concerning hypnotism, 472; skin-grafting with grafts from the dead subject, 119.
Gland, mammary, echinococcus of, 543; mammary, tuberculosis of, 220; parotid, removal of, 700; thyroid, removal of, 755.
Glands, cervical lymphatic, tuberculous degeneration of, 720.
Glaucoma, 216, 329.
Glio-sarcoma, of the cerebellum, 719.
Glomerulo-nephritis, 349, 586.
Goertz, Dr. Adolph, 586.
Goitre, exophthalmic, 65; retropharyngeal, 125.
Goldsmith, Dr. M., pigeon-lice infesting the skin of a woman, 501.
Gonorrhœa, 52; the internal administration of chlorate of potash in, 291.
Gout, 458; diet for, 640; insomnia in, 463.
Gowers, Dr. W. K., notice of book by, 17.
Green, Dr. Samuel A., 700.
Greene, Dr. William Warren, notice of death of, 443; the causes of failure in obtaining union in operating wounds, 537.
Griscom, the Chicago faster, 27, 112, 195.
Gross, Dr. S. W., notice of book by, 522.
Growths, laryngeal, moral of, 259.
Green, asst. surg., notice of death of, 390.
Guiteau's defence, 658, 587.
Guiteau: is he insane? 464, 529, 500, 556; expert testimony for the prosecution in trial of, 743; mental condition of, 714; trial of, 603, 630.
Gulf-weed, in epilepsy, 726.
Gundry, Dr. Richard, 528.
Gunpowder, removal of, from the skin, 748.
Gymnastics, pulmonary, 487.
Gynomania, 140.

H

Hæmatocele, retro-uterine, 377.
Hadden, Dr. Alexander, treatment of subacute and chronic gout, 458.
Hallucinations, and central localization, 260.
Hamamelis, 175.
Hammond, Dr. Græme M., nerve-stretching as a radical cure for pain, 180.
Hammond, Dr. Wm. A., a word for Dr. Beard, 446; notice of book by, 16; the condition of the arteries after death, 668.
Hanahan, Dr. R. B., successful removal of a subperitoneal uterine fibroid, 710.
Hands, deformity of, from a burn, 665.
Harman, Dr. G. A., do the auricles actively contract? 94.
Harris, Dr. Vincent, notice of books by, 271, 660.
Harvey statue, 267.
Hay fever, 222, 572.
Head, decrease of size of, 473; human, size of, 279; injuries to the, 477.
Headaches, 386.
Head-mirror, question of priority, 308.
Health, of school children, 558.
Health Officer of the Port of New York, 194.
Hearing, capacity of, in children, 545.
Heart, aneurism of the, 313, 362; circulation in the, Brücke's theory disproved, 308; concentric hypertrophy of left ventricle of, 356; diseases of, treatment, 629; hypertrophy of, 586; hypertrophy of, in Bright's disease, 608; rupture of, 553; valvular ruptures of, 409.
Heart-beat, mechanism by which it is regulated and maintained, 333.
Heart-sound, causation of the first, 392.
Heart-sounds, reduplication of, 487.
Heart's action, spontaneous and sudden acceleration of, 551.
Heat, animal, 333; disinfection by, 40; fatality from, 336; instrument for measuring the production of, in living bodies, 155.
Hemeralopia, in hepatic diseases, 392.
Hemiatrophy, facial, 95.
Hemiglossitis, right, 416.
Heminumbness, intermittent post-malarial, 695.
Hemisphere, cerebral, destructive lesion of the left, 19.
Hemiplegia, intermittent, 695; osseous lesions in, 741.
Hemorrhage, best means for arresting, in extirpation of the tongue, 300; cerebral, resulting in "crossed" paralysis, 677; effect upon the blood produced by, 306; puerperal, 324; retro-peritoneal, 635.
Henry, Dr. M. H., clinical observations on the value of iodide of potassium in the late lesions of syphilis, 590.
Hepatitis, interstitial, 531.
Hepatotomy, 125.
Hernia, 77, 598; diaphragmatic, 378; inguinal, 161; of the ovary, 319; of the umbilical cord, 376.
Herpes, pharyngeal, 68.
Heschl, Dr., notice of death of, 41.
Hiccough, 573.
Hip disease, practical point in the mechanical therapeutics of, 667.
Histology, of the lung, 68.
Hodgkin's disease, and leucocythæmia, 740.
Holden, Dr. Luther, notice of book by, 522.
Holgate, Dr. Thomas H., instrument for measuring the lower extremities correctly, 164.
Holmes, Dr. Gordon, notice of book by, 414.
Holmes, Dr. O. W., 55.
Homœopaths, and regulars in the same hospital, 738; consulting with, 503, 575, 583, 615.
Homœopathy, 273; and allopathy, 352; and the British Encyclopædia, 56.
Horses, 489.
Hospital, a Garfield memorial, 471; Woman's, in Newark, 737.
Hospital of the University of Pennsylvania, 66, 121, 681, 737.
Hospital Saturday and Sunday, 686, 714.
Howard, Prof. E. Lloyd, 644.
Hungarian, the sleeping, 56, 224.
Hunt, Dr William, the post-mortem examination of President Garfield, 642; blood from the splenic artery, 721.

Hunter, Dr. Chas. H., can a man graduate without having seen a case? 49.
Huxley, Prof., 223.
Hydrangea, in renal calculus, 652, 659.
Hydrocele, 66, 628; in the female, 406; treated by chloride of zinc, 544.
Hydrocephalus, peculiar case of, 306.
Hydrophobia, 432, 532; prevention of, 251; simulated by acute alcoholism, 28.
Hydruria, and polyuria, 656.
Hygiene, annual report on, 492.
Hyoscyamine, in diseases of the mind, 654.
Hyperæsthesia, of the ovary, 182.
Hypertrophy, concentric, of left cardiac ventricle, 356.
Hypodermic medication, 614.
Hypophosphites *versus* phosphites, 696.
Hypnotism, 260, 472
Hysteria, 680; static electricity in, 713.

I

Ice-cooler, 165.
Ichoræmia, 418.
Illinois State Medical Society, 101.
Impotence, static electricity for, 592.
Impregnation, artificial, 56.
Immersion, recovery after twelve minutes, 525.
Incapacity, testamentary, 260.
Incubation, of the communicable diseases, 55.
Index Catalogue of the Library of the Surgeon-General's Office, U.S.A., notice of, 157.
Indiana State Medical Society, 52.
Inebriety, as a disease, 643; clinical studies of, 341, 427; trance state in, 561, 585.
Infants, systematic weighing of, 517.
Inflammation, croupous, of the middle ear, 95; croupous, of Steno's duct, 220; inunction as a remedy for, 63; of arteries, 12; phlegmonous, of the maxillary, frontal, and sphenoidal sinuses, 349; scrofulous joint, 326.
Infection, malarial, influence on pregnancy, 544; puerperal, in the male, 544.
Inhabitant, the oldest, 417.
Inhalations, value of medicinal agents, 319.
Ingals, Dr. E. Fletcher, aneurism of the heart, 313.
Injection brou, 389; hypodermic, of water for pain, 418; intravenous, of ammonia, 53; vaginal, death from, 28.
Injections, hypodermic, 279.
Inoculation, new experiments in preventive, 155; of both eyes, for pannus, 4; prevention of disease by, 99.
Insane, care of, 260, 304; care and treatment of, in England, 211.
Insanity, alleged increase, 559; and malaria, 194; and quinine, 532; from pressure, 572; increase of, in New York, 221; in its relation to other diseases, 261; resulting from syphilis, 629.
Insecticide, delphinium as an, 655.
Insomnia, 279; in gout, 463.
Inspectors, sanitary, in New York, 473.
Insufficiency, of the internal recti muscles, 217.
Insurance, life, and overlosing, 223.
Intestine, rupture of, 526, 545.
Intestines, illustrating aggravated lesions of typhoid fever, 524.
Inunction, as a remedy for inflammation, 63.
Io line, tincture of, and the chlorated tincture of, 537.
Iodoform, in catarrhal diseases, 52; in tubercular disease of the bones and joints, 220.
Iowa State Medical Society, 24.
Iridotomy, 216.
Iritis, syphilitic, 113.
Iron, perchloride, of, 583; tincture of, in capsules, 700.
Irritant, action of an, 18.
Irritation, genital, 569, 575, 576, 693.

J

Jackson, Dr. A. Reeves, carbolized catgut ligatures for laceration of the cervix uteri, 675.
Jackson, Dr. J. B. S., 55.
Jacobi, Dr. A., Rudolf Virchow, 449; Virchow's tribute to American military medicine, 501.
James, Dr. J. Henry, stricture of the stomach, 193.
Jarvis' operation, in hypertrophic nasal catarrh, 29, 479.
Jaw, Esmarch's operation for contraction of, 152; lower tumor of, 604.
Jejunum, rupture of, 662.
Jennings, Dr. C. G., two cases of tracheotomy, 370.
Johnson, Dr. Laurence, notice of a book by, 45.
Johnson, Dr. Woolsey, 755.
Joints, excision of, 244; tubercular disease of, early resection in, 183.
Joint diseases, of the lower extremities, axillary and ischiatic support in, 1.
Jones, Dr. Geo. E., a new needle-holder, 528.
Jones, Dr. Henry E., a phenomenon of partial morphia-narcotism, 734.
Jones, Dr. S. S., American Academy of Medicine, 582
Jones, Dr. Talbot, cerebral hemorrhage resulting in "crossed" paralysis, 677.
Journal of mental and nervous diseases, 700.
Judkins, Dr. William, a new apparatus for preparing plaster-of-Paris bandages, 753.
Judson, Dr. A. B., the question of axillary or ischiatic support in the treatment of joint diseases of the lower extremity, 1.

K

Kane, Dr. H. H., the Chinese opium-pipe as a therapeutic agent, 511.

Osteomyelitis, spontaneous, 683.
Otis, Dr. G. A., 699.
Otitis, suppurative, 218.
Ovarian, cyst, double, 357.
Ovaritis, 488.
Ovary, hernia of, 319; neuralgia and hyperæsthesia of, 182.
Ovaries, apparent, absent with undeveloped uterus, 652.
Ovariotomy, during pregnancy, 712.
Ovum, abortive, 496.

P

Pachymeningitis, chronica, 746; hemorrhagica, 159.
Page, Dr. C. E., notice of book by, 101.
Page, Dr. R. C. M., metastatic parotitis, 281.
Paget, Sir James, 194; pain, cured by hypodermic injection of water, 418; nerve-stretching for, 180.
Pancreas, affections of, and diabetes, 657; primary cancer of, 518.
Pannus, inoculation for, 4.
Papaiva, 725.
Paracentesis, abdominis, repeated, 125; of the pericardium, 653.
Paralysis, general of the insane, tendon reflex in, 17; infantile spinal, 433; of malarial origin, 693; peripheral, from pressure, 19; post-diphtheritic, 22; treatment of cerebral, 307.
Paralysis agitans, 713.
Parangi, 632.
Paraplegia, intermittent, 695.
Parotiditis, and orchitis, 27; metastatic, 281, 475; pyæmic, 639.
Parsley, for suppressing the secretion of milk, 588.
Parvin, Dr. Theophilus, 644.
Patella, fracture of, 627.
Patella-hooks, 165.
Pathological conditions, curious, 368.
Pathology, experimental, 204.
Peabody, Dr. Geo. L., notice of book edited by, 298.
"Pearl, a therapetuic, at random strung," 386.
Peck, Dr. E. S., inoculation of both eyes for complete pannus with gonorrhœal pus, 4.
Pellagria, 413.
Pellets, cupric test, 55.
Pelvis, adenitis of cellular tissue of, 5.
Pemphigoid, 737.
Penis, epithelioma of, 303.
Pepper, Dr. William, uterine chloasma in contrast with Addison's disease, 535.
Pepsin, as a solvent for diphtheritic membrane, 616.
Percussion and auscultation, 248.
Pericarditis, septic, 746; tubercular, 362.
Pericardium, paracentesis of, 656.

Pericystitis, suppurative, 355.
Peritonitis, caused by rupture of gall-bladder, 587; puerperal, 443.
Peritoneum, fresh and dead tissues in, 41.
Pertussis, ethiops mineral in, 414.
Pessary, Nussbaum's flesh, 27; retained ten years, 718.
Petroleum, in phthisis, 27.
Phalanges of the middle finger, resection of, 303.
Pharmacopœia, hints from the homœopathic, 267; international, 334.
Pharynx, dermoid tumor of, 76; herpes of, 68; sarcoma of, 407; stenosis of, 260.
Phelps, Dr. A. M., the treatment of talipes by open incision, 337.
Phinney, Dr. A. B., a new treatment for epithelioma, 48.
Phosphates *versus* hypophosphites, 696.
Phthisis, acute, topical medication in, 41; diarrhœa of, treatment of, 308; influence of pneumo-hydrothorax on, 712; inhalations, antiseptic, in, 709; petroleum in, 27, 80; nausea and vomiting of, 738; pulmonary, and menstruation, 657; the Adirondack cure for, 490; without cough, 55.
Physicians, decrease in the number of, in Prussia, 736; female, 111.
Physic and surgery, the New York statutes for regulating the practice of, 6, 36.
Physiology, 263; and materialism, 127; of the phenomena of trance, 85.
Picrotoxide, 672.
Piffard, Dr. H. G., weak spots in our materia medica, 429.
Pigeon-lice, infecting the skin of a woman, 501.
Pigment in the sputum, 182.
Pilocarpine, 335, 599; and atropia-poisoning, 41; in croup, 756; in diphtheria, 598; in scarlet fever and diphtheria, 152; in uræmia following scarlatina, 376.
Placenta, condition of the site of, 692.
Pleuritis, 683; in children, 129; thoracentesis in, 418.
Pleuro-pneumonia, prevention of, by inoculation, 530.
Plumbers, and public health, 223; regulations for, 437.
Pneumonia, 374; from a tooth in a bronchus, 570; treatment of, 283.
Pneumo-hydrothorax, influence of, on phthisis, 712.
Poisoning, by bologna sausage, 112.
Poole, Dr. Thomas W., curare and motor-nerve endings, 138.
Poore, Dr. C. T., osteotomy for genu valgum, 172.
Polypus, nasal, 356, 368; naso-pharyngeal, 106, 551.
Polyuria, and hydruria, 656.
Pomeren, Dr. Joel, notice of death of, 390.
*Popular Science Monthly* and quack advertisements, 671.
Porter, Dr. George Whipple, 112.
Porro's operation, 728.
Potassium, bromide of, in cardiac diseases, 629; bromide of, large doses of the, 627; bromide, peculiar effect of, in insane epileptics, 18; chlorate of, internal use of, in gonorrhœa, 291; iodide of, in the etiology of Bright's disease, 435; iodide of, in the treatment of cardiac diseases, 629; iodide of, large doses of, in the late lesions of syphilis, 590; permanganate of, as an antidote to the venom of the serpent Bothrops, 560; permanganate of, in serpents' bites, 656.
Potts' disease, 175.
Powell, Dr. Seneca D., a new dilator, 723.
Practitioner, experiences of a country, 584.
Practitioners, unlicensed, 387.
Prescriber's Memoranda, notice of, 354.
Pregnancy, and caries of the teeth, 416; and the decidual cell, 292; aphorisms, 504; complicated with ovarian cyst, 552; extra-uterine, gastrotomy for, 519; influence of malaria on, 544; nephritic affections that complicate, 628; ovariotomy during, 712; renal lesions in, 685.
Prenatal culture, 688.
President Garfield's case, 42, 57, 71, 100, 112, 128, 139, 154, 166, 185, 199, 226, 269, 295, 321, 350, 380, 410, 621; autopsy, official bulletin of the, on the body of, 364, 399, 642; malpractice in the case of, 600; professional fees, 574; report of the case of, 393; room, how it is cooled, 224; wound, location of bullet in, 196, 222.
Prizes, Belgian and Italian, 390; offered by the French Academy, 491.
Prize committees, 184.
Probes, electrical, and forceps, 195.
Probing wounds of cavities, 612.
Proceedings of the Connecticut Medical Society, 691.
Process, the supracondyloid, and hereditary transmission, 241.
Prostate gland, total extirpation of, 291.
Prostatitis, acute suppurative, 291.
Prudden, Dr. T. Mitchell, notice of book by, 604.
Pulse, rhythm of, 533; slow, 504, 533, 670.
Purgatives, by hypodermic injection, 112.
Purcell, Dr. F. A., notice of book by, 353.
Pus, gonorrhœal, in inoculation for pannus, 4.
Pustule, malignant, 572.
Putnam's Sons, Masse's anatomical plates, 286.
Putzel, Dr. L., injuries to the head, 477.
Pyæmia, what is it? 277.
Pyelitis, chronic catarrhal, 89.
Pyer's patches, "shaven-beard" appearance, 633.
Pylephlebitis, suppurative, in a child, 13.
Pylorus, cancer of, 306; excision of, 167.
Pyoneumothorax, feculent, 291.

Q

Quarantine, the value of, 250.
Quebracho, in dyspnœa, 304, 559; in exophthalmic goitre, 65.
Quinine, absorption and elimination of, 97; and insanity, 532; and the cinchona alkaloids, 25; large doses of, followed by loss of vision, 217.

R

Rabies, 644.
Ranney, Dr. Ambrose L., notice of atlas, 298.
Ranula, 183.
Raynaud, Prof. Maurice, notice of death of, 194.
Rectum, extirpation of the lower end of, 145; foreign body in, 390; stricture of, 482.
Red Cross Society, an American, 72.
Redemeir, brain of the murderer, 388.
Registration, statistics of, 258
Regnard, P., notice of book by, 745.
Regulars and homœopaths, in the same hospital, 738.
Reiche, Dr. P. H., inversion of the uterus, 91.
Reichert, Dr Edward T., reply to Dr Poole, 49.
Religion, and nursing, 644.
Renal disease, 249.
Reputation, the value of, 547.
Resection, early in tubercular disease of the joints, 183.
Resurrection, 392.
Retina, concussion of, by a bullet, 217; detachment of, treated with pilocarpine, 329; sarcoma of, 158.
Retractor, automatic tracheal, 724.
Reynolds, Dr. Dudley S., the treatment of nasal polypi by injection, 368.
Rheumatism, acute articular, 657; and chorea, 327; subcutaneous nodules in, 327; with mania a potu, 65.
Rhythm, "galloping" cardiac, 97.
Riband, Dr. J. Gaspard, notice of death of, 503.
Riggs, Dr. B. H., dislocated spleen, 752.
Robbins, D. C., the consumption of quinine and the cinchona alkaloids, 25.
Roberts, Dr. John B., notice of book by, 494.
Rockwell, Dr. A. D., franklinic or static electricity, 317.
Roosa, Dr. D. B. St. John, 53; foreign bodies on the conjunctiva or cornea, 421; the removal of foreign bodies from the ear, 645.

Roosevelt Hospital, 345.
Rötheln, epidemic, 101, 262, 327.
Rubeola, and measles, 551.
Rush Medical College, 112.
Rye, head of, discharged from an abscess of the chest, 305.

S

Salaam, spasmodic, 417.
Sanitary exhibition in New Jersey, 437; international, in Berlin, 756.
Sanitary supervision, of public schools, 631.
Sansom, Dr. Arthur E., notice of book by, 493.
Sarcoma, of the mamma, 384; of the pharynx, 407; small-celled of the retina and choroid, 158; of spleen, 123; of the thigh, 158, 355.
Satterthwaite, Dr. T. E., notice of book edited by, 493.
Scabies, 288.
Scala media cochleæ, 95.
Scarlet fever, pilocarpine in, 153.
Scepticism, in medicine, 227.
School system, the American, 547.
Schools, public, sanitary supervision of, 631.
Schweig, Dr. Geo. M., the relation of urethral stricture to sexual debility, 624.
Sciatica, treated with hypodermics of nitrate of silver, 713.
Sclera, penetrating wound of, 550.
Scrofulous, neck, 248.
Scurvy, pathogenesis of, 379.
Sea-air, and infantile diarrhœa, 139.
Sea-sickness, and local anæsthesia, 531; ergot in, 389; the bromides in, 214.
Searle, Dr. W. S., notice of book by, 299.
Seguin, Dr. E. C., importance of the early recognition of epilepsy, 141, 169; methods of diagnosis in diseases of the nervous system, 617, 701.
Seiler, Dr. Carl, Jarvis' operation, 479.
Sensibility, influence of sinapisms on, 435.
Septicæmia, from a leech-bite, 418.
Sewerage, and storm-water, 12.
Sewer-gas, ventilating-trap for the prevention of, 96.
Sewers, ventilation of, 726.
Sexton, Dr. Samuel, acid boracicum and calendula in aural disease, 729, 749; dental sound transmission—the Japanese otacoustic fan, 286; Eustachian catheter, 82; the effect on the ear of high atmospheric pressure in tunnel-construction, 137.
Sexual instinct, abuse of, in females, 593.
Shrady, Dr. Geo. F., presentation to, 23; surgical and pathological reflections on President Garfield's wound, 404.
Silver, iodide of, in conjunctivitis, 598; nitrate of, hypodermically, in sciatica, 713; phosphate of, 168.
Sinapisms, influence of, on sensibility, 435.
Sinuses, cerebral, 242; inflammation of the maxillary, frontal, and sphenoidal, 349.
Skin, pigeon-lice infesting the, of a woman, 501; removal of gunpowder from, 748; treatment of affections of, by occlusion, 97.
Skinner, Dr. J. O., disorganization of the lung, with fatal hemorrhage into the pleural cavity, 735.
Skin-grafting, from the cadaver, 119; in etiology of syphilis, 756.
Skoda, Prof., anecdotes of, 167; autopsy of, 221.
Skull, depressed fracture of, in etiology of insanity, 572; human, the primordial cartilage of, 241; fracture of, 633; measurements of, 224; tumors of, resection of, 290.
Small-pox, and the efficacy of vaccination, 140; Chicago, 672; in the West, 699; spreading, 716
Smith, Dr. Andrew H., indications for the treatment of naso-pharyngeal catarrh, 147.
Smith, Dr. David P., 26.
Smith and Marshall, notice of book by, 691.
Smythe, Dr. A. G., decrease of size of head, 473.
Social science themes, 320.
Society of German Naturalists and Physicians, 585.
Soda, and calomel, 28.
Somnolence, prolonged, 381.
Sound-transmission, dental, 286.
Sound-transmitter, the dental, 288.
Souffle, cephalic, of adults, 654.
Spasm, ciliary, of central origin, 21; irritant, 417; of the bladder, 375.
Specialism, in medicine, 104.
Spider, the, as an antiperiodic, 385.
Spider's web, as an antiperiodic, 94.
Spine, caries of, diagnosis of, 348.
Spitzka, Dr. E. C., automatism, in an epileptic, 733; microcephalus, 48; the progress in neuropathology, 363.
Spleen, dislocation of, 752; sarcoma of, 123.
Sphygmograph, the, in the diagnosis of aneurism, 115.
Sputum, myelin and pigment in, 182.
St. Luke's Hospital, 644.
St. Mary's Hospital, London, 486.
Stair, Dr. J. B., consultation with homœopaths, 583.
State Board of Health, 221, 321, 584, 603; of Connecticut, third annual report of the, notice of, 297; of Rhode Island, notice of report, 691; of Wisconsin, notice of report, 691.
State Medical Society of Nebraska, 270.
Statue, of Harvey, 267.
Statutes, for regulating the practice of physic and surgery, 6.
Statistics of registration, 258; vital, of Massachusetts, 560.
Steno's duct, croupous inflammation of, 220.
Stenosis, œsophageal, 418; of the pharynx, 230.
Sterility, in the male, 56.
Sterling, Dr. Wm., notice of book, 354.
Sternberg, Dr. George M., an instructive experiment, 339.
Stethoscope, a new binaural, 279.
Stevens, Dr. John H., notice of death of, 700.
Stillman, Dr. Charles F., an aid to the mechanical treatment of weak ankles and inverted feet, 309.
Stillman, Dr. Charles H., obituary, 697.
Stomach, action of coffee and sugar on, 387, 573; cancer of, 634; rupture of, 599; stricture of, 193; the position of the, 241; wounds of, 476.
Stone, extraction from the bladder, 243; operations for, 31.
Storm-water, and sewerage, 12.
Stowell, Dr. Chas. H., notice of manual by, 297.
Strabismus, convergent, 113; intermittent concomitant divergent, 217.
Strangulation, intestinal, 382.
Stricture, of the rectum, 482; of the stomach, 193; progressive, at the ileo-cæcal junction, 515, 523; urethral, relation of, to sexual debility, 624.
Strychnia, as an expectorant, 334; in myelitis, 19.
Strychnia-poisoning, chloral in, 306.
Student-life in Vienna, 373.
Sugar, and albumen in the urine, 407.
Sunstroke, 334.
Surgeon-General of the Army, annual report of, 584.
Surgeons, dental, in the army and navy, 689.
Surgery and physic, statutes regulating the practice of, 6.
Surgery, antiseptic, 280; changes which it has undergone during the last ten years, 253; military, 262; peritoneal, the progress of, 466, 487.
Surgical and pathological reflection on President Garfield's wound, 404.
Surgico-anatomical study of President Garfield's wound, 402.
Sutures, carbolized catgut, for laceration of the cervix uteri, 675.
Swift, Dr. Geo. M., 345.
Sympathetic nerve, 124.
Symptoms, ocular, in different diseases, 96.
Syphilis, action of mercury in, 505; as a cause of locomotor ataxia, 245; cerebral, 552; cutaneous, illus-

trations of, notice of, 157; hereditaria tarda, 551; hypodermic use of mercury in, 684, 728; inoculated by skin-grafting, 756; insanity from, 629; late manifestations of, 409; of orbital walls, 554; secondary, 431; spontaneous fractures in, 684; sudden deafness from, 517; vaccinal, 644; value of large doses of iodide of potassium in the late stages of, 590; visceral, 433; with tubercle and gout, 245.
Syphilitics, traumatism in, 489.
Syphiloderms, flat pustular, 738.

T

Table-hygiene, Abernethy on, 309.
Talipes, 337.
Tannin, administration of, 504.
Tarsus, caries of, 632.
Taste, perverted, in the fowl, 28.
Taylor, Dr. Henry Ling, Pott's disease, 175.
Teale, Dr. T. Pridgin, notice of book by, 354.
Teeth, caries of, and pregnancy, 416; replantation and transplantation of, 331; syphilitic alterations of, 292.
Temperatures, puerperal, 741.
Tendon reflex, 17, 417; in diagnosis of diseases of the spinal cord, 433.
Tension, mental, 569.
Tensor tympani, sound produced by the contraction of, 140.
Testicle, congenital dislocation of, 362; removal of, 152.
Testicles, four, 390.
Tetanus, 637; in Baltimore, 419; traumatic, and calabar bean, 319; treatment, 166.
Theatres, fires in, 687; inspection of, 716.
Therapeutics, alcohol in, 653; mechanical, of hip disease, 667.
Thermograph, 629.
Thigh, pistol-shot wound of, 636; sarcoma of, 355.
Thomas, Dr. N. G., diet for gouty patients, 640.
Thyroid, cancer of the, 303.
Thrombosis, of the inferior vena cava, 376.
Tinctura ferri chloridi, 84.
Tissue, cellular, of the pelvis, adenitis of, 5; nervous, pathological specimens of, 261.
Tissues, fresh and dead, in serous cavities, 41.
Tobacco, a parable, 307; prizes against the abuse of, 756; the anti-society in France, 307; therapeutic use of, 40.
Tooth, in a bronchus, 570.
Tongue, best means for arresting hemorrhage in extirpation of, 300; epithelioma of, 302; fatty tumor of, 183.
Trachea, fibro-sarcoma of, 543; mycosis of, 183.
Tracheal retractor, 724.
Tracheotomy, 370.
Trachoma, 4.
Trade-mark, monopoly system, 110; system, 162.
Trance, and trancoidal states in the lower animals, 11; physiology of the phenomena of, 85; state of, in inebriety, 561, 585.
Transactions of the American Gynecological Society, notice of, 690; of the College of Physicians, Philadelphia, notice of, 522; of the Illinois State Medical Society, 100; of the Medical Society of Virginia, notice of, 101; of the State Medical Society of Wisconsin, 297.
Transfusion, of blood, 639; peritoneal, 390.
Traumatism, in syphilitics, 489.
Trap, ventilating, for sewer-gas, 96.
Trephining, in epilepsy, 277; of the ilium, in psoas abscess, 628.
Trichinæ, in fish, 391; in New Orleans, 221.
Tri-medical Society, 549.
Tuberculosis, and lupus, 519; communicated by milk, 326; of the mammary gland, 220.
Tumor, dermoid, of the pharynx, 76; fatty, of the tongue, 183; intracranial, 48; multilocular ovarian, 78; of the lower jaw, 604; lymphatic glandular, 189; sangineous, of the right vocal cord, 629.
Tumors, cutaneo-venous, 683; erectile, 521; of bones of the skull and the meninges, resection of, 290; intraperitoneal, 242; neoplastic, resolution of, 656; nomenclature of, 249; ovarian, point in diagnosis of, 324.
Tuning-fork in diagnosis, 219.
Turnipseed, Dr. E. B., President Garfield's case, 621.
Tyson, Dr. James, notice of book by, 207.

U

Ulcer, gastric, 307.
Ulna, subperiosteal excision of, 194.
Universities, German and Swiss, 756.
University of Berlin, 280.
Uræmia, etiology of, 627; following scarlatina, pilocarpine in, 376.
Urethra, and bladder, absorptive powers of, 377; prolapse of the female, 174; rapid dilatation of, for removal of calculus, 348; stricture of, with polypi, 148.
Urethritis, chronic, 375; is there a specific disease, 559.
Urethroscopy, at Vienna, 347.
Urethrotomy, external, 151.
Urine, albumen and sugar in, 407; experiments with, 339; fat in, 627; in chronic Bright's, 607.
Uterus, atrophy of, treated by electricity, 737; double-bodied, 626; intermittent contraction of the pregnant, 323; inversion of, 91; liniment in prolapse of, 741; partial inversion of, 444; rupture of, treated by drainage, 290; ruptured, removal of, 84; subperitoneal fibroid, 710; total extirpation of, 324; undeveloped, and electricity, 280; undeveloped, with apparent absence of ovaries, 653.
Utero-gestation, prolonged, 552.

V

Vaccinating, for splenic fever, 583.
Vaccination, 194, 587; and leprosy, 194; and small-pox, 140; and vaccine virus, 130; does it protect? 602; in cutaneo-venous erectile tumors, 683; obligatory in France, 280; Pasteur's, 750.
Vaccine virus, 53.
